Addresses

CERTAIN PHASES OF RECENT WORK IN PATHOLOGY AND PHYSIOLOGY.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON PATHOLOGY AND PHYSIOLOGY AT THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, BOSTON, JUNE 5-8, 1906.

HENRY A. CHRISTIAN.
BOSTON.

In accordance with the by-law of the American Medical Association the privilege is accorded to me, as Chairman, of opening this annual session of the Section on Pathology and Physiology. Moreover, I am geographically in a position to extend to you, its members, a welcome to the city of Boston and more especially to the laboratories of our medical schools and hospitals, and this I most cordially do. It is the privilege this year of the Section to have as guests Prof. von Frey of Würzburg and Professor Mills of Montreal. To them, in the name of the Section, I extend a hearty welcome and a cordial invitation to take part in all of the proceedings. We feel honored by their presence and anticipate much pleasure and profit from the addresses with which they are to favor us.

On this occasion it has seemed to me fitting briefly to call attention to certain phases of recent American work in pathology and physiology. It is not my intention to give a critical review of any special researches nor to attempt any enumeration of the recent publications. It is the general aspect of the work, not the work in detail, of which I wish to speak, and more particularly of that which in a sense represents some departure from the type of work done in earlier days.

Our medical laboratories may be grouped in four classes: 1, Government laboratories; 2, medical school laboratories; 3, hospital laboratories; 4, independent endowed laboratories.

Of government laboratories we have two classes, national and municipal. Medical laboratories under national supervision represent a recent development in the United States. Many of the departmental laboratories at Washington are indirectly associated with medical science. Those concerned in the standardization of antitoxin, drugs, and foodstuffs are of great importance to the medical profession, but it is medical investigation with which we are now most concerned, and in these lines some creditable work is being done at Washington.

The government laboratories at Manila have gradually grown out of the necessity of an army and navy occupation. Now they occupy a large, new, well-equipped building, forming an extensive plant, active in work. The investigations there of amebic dysentery, plague and other tropical diseases serve as types of their work and amply justify their existence. The facilities they furnished to the recent Harvard expedition for the study of experimental variola and vaccinia illustrates another form of their usefulness. With the extension of social and commercial relations between the United States and the tropics, as is inevitable with the possession of tropical colonies, a knowledge of tropical diseases will become of greater importance and our medical schools will be compelled to teach tropical medicine. Such laboratories as those at Manila should be able to furnish material for such courses and the facilities for our teachers to gain there some first-hand knowledge of the subject. An interchange of material and frequent expeditions should be of such great mutual advantage that the government could afford to furnish transportation and quarters each year for a few of our laboratory workers, and thus give a great stimulus to this branch of medicine in America. Unless this be done these laboratories, in a sense, will fail to accomplish their highest good.

Another form of government activity has been the equipping of commissions for the investigation of special problems. The brilliant results of the commission for the investigation of yellow fever are still fresh in our minds and their vast importance should serve as an incentive for much future work. The recent appropriation for the establishment of a station for the investigation of leprosy in the Hawaiian Islands, to be thoroughly equipped for scientific work and under the direction of a trained investigator, is a type of national government activity along these same lines.

Municipal laboratories have long been in existence in connection with boards of health and their routine work is of almost daily use to every medical man. However, only in recent years has medical investigation been a part of their work, and even now investigation is carried on in but few. The work of the New York City Board of Health, from whose laboratory much scientific work of merit has been published, should serve as an example in this respect to many other municipal laboratories. To serve its highest function, the muncipal laboratory must investigate as well as carry on routine examinations.

Medical school and hospital laboratories are in many cases very intimately associated. Their establishment came fairly early in America. Still, in the last few years, many new laboratories have been opened and great improvement has been made in both the old and the new, the greatest perhaps in those cases where the union between hospital and medical school has been closest and the stimulus of teaching has been strongly felt. This is a fact which can be scarcely disputed and should not remain without influence on the hospital laboratories as yet unattached to medical schools. Much of the advance in the medical school laboratories has been the result of the gradual extension to the medical school of the university spirit, and this influence, in turn, has been felt in the hospitals. With it has come a higher type of work, more experimental investigation, more search after basic principles.

A very large amount of work, much of it excellent in quality, has been produced in such laboratories. This covers a wide range of subjects. In the hospital laboratory most of this has been along the lines of pathology and chemistry. Physiology has lagged too much in the hospital laboratory, where for the most part it is unrecognized. In this respect development is needed in our clinics and may serve to lessen the present too great breach between laboratory and ward worker.

It would be interesting to recapitulate much of this recent work, but time does not suffice. The work of two laboratories, however, I wish to call attention to. In the laboratory of the University of Michigan valuable studies of the trypanosomes and the spirochetæ have been made. It is particularly noteworthy that there, in an inland town in the north temperate zone, investigations could have been carried on with the result of a distinct advance in our knowledge of a group of diseases of man, most of which are confined to the tropics. The results of this work will extend greatly the range of problems capable of successful attack in the laboratories of this country. In the laboratories of the Johns Hopkins Hospital another phase of medical work is shown. There in a laboratory of experimental medicine pathology, physiology, medicine and surgery have been combined; a form of medical coöperation, if I may be permitted the term, is in operation. Diseased dogs are treated and the student learns medicine and surgery. Diseased conditions simulating those occurring naturally are produced; operative technic is acquired. The immediate and late effects are studied by the methods of physiology and clinical medicine; the end results are studied by the methods of pathology. More exact knowledge of the phenomena of certain diseased conditions and a better understanding of their underlying causes are thus obtained. This is a type of laboratory and work which needs to be developed in many of our hospitals if we are to keep pace with medical science abroad.

Independent endowed laboratories are the latest development of medical science in America. They are represented by the Rockefeller Institute in New York, the Institute for the Study of Infectious Diseases in Chicago and the various commissions for the investigation of cancer. Some are organized for the study of special problems, others may devote their attention to a wide field. Recently a change has been made in the mode of attack of many of these special commissions. Instead of attacking the problem directly as in the earlier days, attention is being given to technical methods and more fundamental biologic principles in the hope of thus securing a new path of approach to the central problem. With this new point of view we hear less of the so-called practical. This query, "What is the practical use of the problem?" has too long been a drag stone to investigation in America. This hindrance, I believe, is now disappearing and as a consequence there is more search for the truths at the root of problems, even though any practical application may seem remote. In fact, advance will come earlier from work along these lines and already some of the most practical applications have been the results of most abstract investigations. This change in point of view, to me, marks a new and important phase of American medical investigation.

During the past few years, undoubtedly, distinct progress has been made in medical science in America. More men and more money than ever before are now devoted to the study of pathology and physiology. The subjects have broadened out until they touch more and more the abstract sciences, on the one hand, and clinical medicine and surgery, on the other. The methods of the laboratory are being applied in the clinic and from the clinic are gathered problems for the laboratory; both use more the methods of pure science. It is to be hoped that these changes mark the dawn of a new era for American medicine. Some of the spirit of this new medicine is suffused through the program for this session, to which I now invite your attention.

TWO DESIRABLE REFORMS.*

C. M. JACKSON, M.D.
COLUMBIA, MO.

At commencement exercises themes concerning the improvement of the medical profession are always appropriate. It is only through the aid of the well-trained young men now entering the profession that we may hope for greater progress in the future.

That there is still plenty of room for improvement in the medical profession can scarcely be doubted. If, indeed, we consider the matter carefully we must reach the paradoxical conclusion that the medical profession of the United States ranks at the same time the highest and the lowest among the great civilized nations. In technical skill our leaders, especially in surgery, are probably the best in the world. On the other hand, owing to the low standards of medical education that have prevailed in this country during the past century, it must be frankly confessed that the rank and file of our medical practitioners average low in proficiency. As a single example of this, I might cite the fact that not one practitioner in ten is able to use the microscope effectively, although this instrument is universally acknowledged to be of great practical value in the diagnosis of a large proportion of diseases.

Conditions are changing, however. We are now in the midst of a great movement which has for its object the improvement of medical education and the elevation of the medical profession. Entrance requirements of the medical colleges have recently been advanced from a common-school to a high-school education, and already it is generally recognized that to this at least two years of preparation in college work must soon be added. The time required by the medical course itself has increased fourfold, and the end is not yet.

Even more important than the increase in the entrance requirements, and in the length of the curriculum, is the change that has taken place in the character of the instruction given in medical schools. Corresponding to the rapid modern development of the medical sciences, laboratories have multiplied. These laboratories in all first-class schools have been thoroughly equipped with expensive apparatus and have been placed in charge of teachers who spend their entire time in instruction and research. Clinical instruction has also greatly improved, and that this also may be placed on a true university basis is one of the hopes of the future.

Most important of all, it seems to me, has been the revolution in the spirit of medical education. The old lecture system has been overturned and modern instruction is planned so that the student may learn by observing, thinking and acting for himself. The research spirit and methods so ably presented by Dr. Dodson[1] at the last commencement exercises of this school are beginning to dominate medical education.

---

* An address delivered at the commencement exercises of the Medical Department of St. Louis University, May 19, 1906.

This research spirit, I believe, merits still greater encouragement. We have in our modern laboratories and clinics the facilities and conditions necessary for research work, at least by members of the faculty. Why not go a step further and make provision for research work by the students? The first of the two reforms which I wish to suggest to-night is along this line. I propose that, with this purpose in view, we revive as a requirement for the degree of doctor of medicine the preparation of a thesis, similar to that now required in European schools. I say revive the requirement, for it was in fact a requirement in the few American medical colleges existing before the Revolutionary war. In some medical colleges the custom of requiring a thesis for graduation was maintained until the latter half of the nineteenth century. These were, for the most part, theses in name only, however, being in reality mere compilations based on no original work.

The provision for real thesis work as a requirement for the degree of doctor of medicine could easily be made. A small amount of time, perhaps three hours a week, could be set aside in the senior year to be devoted to the work. At the beginning of the year each senior could select a topic for his thesis, with the advice of some faculty member, under whose supervision he would work. The thesis, after completion, would, of course, be submitted to the faculty for approval. The subjects selected would naturally vary according to circumstances, and would necessarily be simple in character, so that the work might be completed, the literature reviewed and the results worked up in the form of a written thesis within the limited time at the student's disposal. The necessary material for thesis work is already present in abundance in our laboratories and clinics. Why not utilize it in this way?

The first objection to the plan which is likely to arise is that the curriculum is already overcrowded, and that the medical student has no time for additional work. This objection might be met, it seems to me, by reducing to a slight extent in the senior year the time now required for the usual cut-and-dried courses, so as to give opportunity for a bit of original work. If, however, this be considered not advisable, there is still another possibility: through lengthening the curriculum. A fifth year for the medical course is already being seriously considered, and it is one of the desirable changes we shall doubtless see accomplished within a few years. This fifth year will probably be devoted to advanced clinical work, preferably hospital service, and would afford ample time and opportunity for working up a thesis for the doctorate degree.

A second objection which might be advanced is that students have not, as a rule, the ability to do original investigation for thesis work. That excuse might be valid for students of some schools, but not for those of any first-class school with modern equipment and respectable entrance requirements. Any student can do original investigation who can observe accurately and reason logically. And any student who can not do this should certainly not be allowed to enter the medical profession.

Then, again, it may be urged that the plan of requiring a thesis for graduation would throw an additional burden on the members of the already overworked medical faculty, under whose supervision the work would be done. But if the members of the class were properly scattered there would be very few, perhaps only one or two, under the supervision of each member of the faculty. And what member of the faculty would not be willing to give individual assistance to one or two students who wanted to do advanced work in that department? If necessary the teaching force could, of course, be increased to accommodate the extra work.

A more serious objection in the case of many schools is the lack of library facilities. This is one line of equipment which has as yet been greatly neglected in most medical colleges. It is especially important that files of the leading American and foreign periodicals devoted to the various medical sciences should be accessible in every medical college library. They are valuable for use in all instruction, but indispensable for research. I am glad to observe that the Medical Department of St. Louis University has already made a most excellent start in this direction, and I hope that the authorities and other friends of the university will not fail to lend their support in strengthening this most important feature. It costs money, it is true, but this is only one more proof of the statement that modern medical education is the most costly education in the world.

When all the objections to the plan of a thesis requirement have been met, we still have to consider whether it is really worth while. What advantages are to be derived from the measure? In the first place, the adoption of this plan would stimulate the research spirit throughout the entire medical school. It would tend to discourage that bane of modern medical education, the "cramming" system, and to encourage students to think for themselves. Independent thinking is one of the rarest things in the world. The accumulated experience of the past is, of course, not to be despised or neglected. On the contrary, to teach a student to appreciate properly the knowledge handed down to him, there is nothing so effective as to make him dig out for himself even the smallest nugget from the vast mine of undiscovered knowledge.

Training of this sort is also of great practical value to the future practitioner. It has often been said, but can not too often be repeated, that every case in medical practice is a scientific problem, and that every successful practitioner (whether he realizes it or not) is an original investigator. And if the practitioner has learned the research spirit and methods during his medical course of study his success in practice will naturally be more rapid and certain.

Moreover, although the intrinsic value of the results obtained by the work done for theses would in most cases be small, the final effect of such a requirement would be to increase the quantity and to improve the quality of the scientific work done by practicing physicians. Why is it that the average papers read at the meetings of our medical societies are so poor in quality? It is not from lack of time to prepare them. It is certainly not from lack of material. It is because the average physician does not realize what valuable opportunities for research work exist in connection with his practice. He does not know what observations are of scientific value or how to record them. He does not know where to find, for comparison, similar observations turn, has been felt in the hospitals. With it has come a higher type of work, more experimental investigation, more search after basic principles.

---

[1] The Journal A. M. A., July 8, 1905, p. 83.

A very large amount of work, much of it excellent in quality, has been produced in such laboratories. This covers a wide range of subjects. It costs money, it is true, but this is only one more proof of the statement that modern medical education is the most costly education in the world.

When all the objections to the plan of a thesis requirement have been met, we still have to consider whether it is really worth while. What advantages are to be derived from the measure? In the first place, the adoption of this plan would stimulate the research spirit throughout the entire medical school. It would tend to discourage that bane of modern medical education, the "cramming" system, and to encourage students to think for themselves. Independent thinking is one of the rarest things in the world. The accumulated experience of the past is, of course, not to be despised or neglected. On the contrary, to teach a student to appreciate properly the knowledge handed down to him, there is nothing so effective as to make him dig out for himself even the smallest nugget from the vast mine of undiscovered knowledge.

Training of this sort is also of great practical value to the future practitioner. It has often been said, but can not too often be repeated, that every case in medical practice is a scientific problem, and that every successful practitioner (whether he realizes it or not) is an original investigator. And if the practitioner has learned the research spirit and methods during his medical course of study his success in practice will naturally be more rapid and certain.

Moreover, although the intrinsic value of the results obtained by the work done for theses would in most cases be small, the final effect of such a requirement would be to increase the quantity and to improve the quality of the scientific work done by practicing physicians. Why is it that the average papers read at the meetings of our medical societies are so poor in quality? It is not from lack of time to prepare them. It is certainly not from lack of material. It is because the average physician does not realize what valuable opportunities for research work exist in connection with his practice. He does not know what observations are of scientific value or how to record them. He does not know where to find, for comparison, similar observations already recorded in the storehouse of medical literature. He has had no training in bringing his observations and conclusions into shape for presentation and publication. These deficiencies, at any rate in large part, would be supplied by the proposed requirement of original thesis work. There are undoubtedly to-day a great many unproductive physicians who could and would make valuable contributions to the advancement of medical science if some such training had been provided in the medical school.

---

[1] The Journal A. M. A., July 8, 1905, p. 83.

Finally, the requirement of a thesis would add to the value and dignity of the degree of doctor of medicine. The doctor of divinity and the doctor of philosophy must each present a dissertation. The degree of doctor of medicine should represent attainments equally high. A thesis for the doctorate in medicine has long been required in Germany and in most of the other great European nations. America is slow in following their example, but "better late than never." Let it no longer be just to reproach the doctor of medicine with the phrase, *doctor sed non doctus!*

There is a second line of needed reform, without which no extensive improvement of the medical profession as a whole can be expected. The requirement of a graduation thesis is a measure which could be adopted and enforced by any medical college. But this, like the great improvements in various directions already made by many medical colleges, does not insure an improvement of the entire medical profession. As a matter of fact, only a small percentage of the medical colleges have kept pace with the advancing standards. Only a few colleges have had the progressive spirit, the ability and the courage to increase adequately the entrance requirements, to equip and to maintain first-class laboratories and clinics and to insist on a high standard of work. The result has been that the high-class schools often suffer from competition with inferior colleges having low requirements. In accordance with a fundamental law of Nature that all bodies move in the direction of least resistance, medical students tend to flock toward those institutions offering the medical degree for the least expenditure of time, money and energy. Why does this tendency, so clearly detrimental to the public welfare, remain unchecked? Why are the low-grade medical colleges still permitted to grind out annually thousands of unqualified graduates to swell the ranks of the already overcrowded medical profession?

It might be argued that the fault lies with the public; that if the people would refuse to patronize incompetent physicians the inferior medical schools would soon die a natural death. But the people are practically helpless. Even the most intelligent laymen often display a pitiful and disastrous lack of judgment in choosing medical advice. They must trust largely to appearances, and even the most incompetent practitioner usually manages to conceal his defects and to make a fine outward appearance. No, it is impossible for the public to protect themselves individually in medical matters. They must depend on the State for protection.

State protection depends primarily on the medical examining and licensing boards. The responsibility for present conditions, therefore, apparently lies chiefly with the licensing boards of the various states. It is to them that we must look for reform in this line. They, and they alone, have the power to protect the public on the one hand and to encourage the progressive medical colleges on the other. The state examinations may be compared to a dam placed across the channel of a river. The water of the stream rises to a level high enough to overleap the barrier, but no higher. Similarly, in medical education the great majority of medical students will prepare themselves to meet the minimum requirements, but no more.

It is but just to the state boards, however, to remember that they have had many difficulties to contend with. All of them, moreover, have improved, and in some states, notably New York and Michigan, they have materially advanced the cause of medical education. I do believe, however, that the majority still lag far behind what ought to be the minimum requirements.

The particular deficiency which I desire to point out in this connection concerns not the thoroughness but the character of the state examinations. The trouble, it seems to me, is not so much that the examinations are too easy as that they are not of the right kind.

To approach this question intelligently we must bear in mind the purpose of the state examination. It is, of course, to determine whether the candidate is properly qualified to practice medicine—to diagnose and to treat properly the various diseases. Do the state examinations fulfill this purpose? Are they a fair test of a man's ability to practice medicine? It does not require much argument to prove that in this respect they are utterly inadequate.

In this connection I will venture to make what may seem to be a preposterous statement. I believe that any young man with a good memory could in a few months memorize a set of quiz compends, and (if allowed to try) could pass the state board examinations in many states without ever having seen the inside of a medical college. And, furthermore, in some instances, if all reports be true, he need not even have a good memory, provided that he carry the quiz compend in his pocket!

The evils of such conditions need only to be pointed out to be condemned. But the important question is, How should the examinations be changed? Would a set of judicious questions, thorough but fair, and a system of inspection which would exclude cheating meet the requirements? It would doubtless be an improvement, but it would still be inadequate. The trouble is that our present system of written examinations is founded on a wrong principle. Nor would oral examinations (from a mere list of questions) help matters much. The ability to answer questions in this way depends largely on word memory, and word memory is no fair index of ability to practice medicine.

The only real and fair test, it seems to me, is a trial at the thing itself, or something as near to it as possible. Let us see how this principle may be applied. It may be assumed as self-evident, in the first place, that a knowledge of the normal and abnormal structure and functions of the human body is an essential prerequisite to the successful practice of medicine. What, for example, is a fair test of a student's knowledge of the anatomy of the triangles of the neck? It is certainly not the ability to repeat words of description which he may merely have committed to memory from a text-book, but (what is a vastly different thing) his ability to find, recognize, understand and explain the various structures from an actual preparation or on the living body. The same principle holds not only for all the fundamental sciences but even more forcibly for the clinical branches. For example, a student may be able to write a full and accurate description of a disease, and yet fail completely even to recognize that disease when he meets the practical test at the bedside.

A practical examination, therefore, is absolutely necessary to exclude incompetents and to test fairly the candidate's ability to practice medicine. It might not be wise to exclude altogether the usual form of written or oral examinations, for a certain amount of memorization is undoubtedly necessary in medicine. Such tests, however, ought to be made strictly subordinate to the practical tests mentioned.

Conceding the theoretical superiority of such practical examinations, the question now arises as to whether or not it would be possible for the state boards, under present conditions, to carry out such a plan. It seems to me quite possible. The necessary materials could usually be obtained without difficulty. The laboratories of any good medical school could readily furnish whatever specimens and apparatus might be necessary to test the candidate's knowledge of the fundamental sciences. Similarly, arrangements could doubtless be made with public or private hospitals for the use of material for the practical clinical examinations.

The greatest difficulty would doubtless be the increased amount of time necessary to conduct the examinations. Such examinations would necessarily consume much more time than the present plan, for they would be largely individual in character. As a necessary consequence the examinations would also be much more costly. But they would be well worth the additional cost, whether this cost be borne by the state or by the individual applicants.

That such a plan is entirely practicable is shown by the experience of Germany, where the state examinations are of such a practical character. In Germany there is an additional improvement, in that the state examinations are divided into two parts. The first examination, the *tentamen physicum,* comes at the end of the first two years of the medical course and covers the fundamental branches. The second and final examination at the end of the course is exclusively clinical in character. The advantage of this plan is that the student must have satisfactorily completed the work in the fundamental sciences before he is allowed to proceed with his clinical work. Many incompetents are thus weeded out at the end of the first two years.

If Germany can carry out a plan so cumbersome and costly, and yet so effective, why can not we? Is human life any less valuable here than there? The adoption of some such plan by our various states would be of the utmost value in the improvement of the medical profession. It would encourage higher medical education and protect the health and lives of the people.

IMPRACTICABILITY OF INTERSTATE RECIPROCITY.*

EDWIN B. HARVEY, M.D.
Secretary of the Massachusetts Board of Registration in Medicine.
BOSTON.

Interstate reciprocity, so-called, has been discussed to some extent in every convention of this organization during the last decade. It has survived the storms of debate for so many years from the fact, no doubt, that it possesses some features of interest to certain members of the profession, some problems which have been labored with, but not yet solved to the satisfaction of all, and which may not be in the discussions of to-day. It is a trite saying that no question should be settled until settled rightly. Our distinguished president, thinking perhaps that further agitation of this subject at the present time might be of interest, asked me a few days ago to write a brief paper for this convention on the impracticability of interstate reciprocity.

Interstate reciprocity should be considered impracticable, however widely practiced, if it does not conserve the broadest needs of society, the protection of the community in the best possible manner against the evils of charlatanism in medical practice. From this standpoint the argument of this paper is drawn.

WHAT IS RECIPROCITY?

The word reciprocity, unfortunately, has been chosen to stand for mutual recognition of medical registration certificates by state boards. This word belongs strictly to the literature of politics. In political circles it is much used at the present time in discussing trade relations between different countries. In such connection it has a well-understood meaning. The *North American Review,* in an article published not long ago, says:

> Reciprocity is only an international form of protection, signifying an equality between the citizens of two countries with respect to the commercial privileges to be enjoyed by each country within the domain of the other.

In this sense the word was first officially used in 1782, in the provisional treaty of commerce between the United States and England. The following may be cited as an illustration of the workings of this principle in international affairs: Canada recently said to the United States, We will allow your cotton goods manufacturers to dispose of the products of their factories in our country without levying duty thereon, provided you will allow our lumbermen to dispose of the products of their mills in your country on the same conditions. The United States replied, Such stipulations are not practicable, for we, too, grow forests and manufacture all the lumber we require for home purposes. The acceptance of your proposition would result in great injury to an important home industry which must be protected in the interests of our own people.

In every instance in international affairs we find that reciprocity has reference only to the importation of such goods or material as the receiving country does not produce at all or only in quantities insufficient to meet the public necessity. Reciprocity in political affairs has an eye ever to the protection of home interests, the prosperity of home institutions. But interstate reciprocity of medical licensure bears a different signification. For example: The state of Maine has a reciprocity clause, so-called, in its registration law. Maine says to New Hampshire, Why should we not reciprocate? We will permit your physicians to locate in Maine and will grant them a license without imposing any restrictions whatever as to their qualifications, provided you will receive our physicians on the same conditions. Such an understanding between two states, in medical parlance, is called reciprocity. But it is not reciprocity in the sense of affording protection. It is a free-trade arrangement wherein the primary object of medical legislation in the states is wholly ignored.

METHODS OF REGISTRATION.

Three methods of registration concern us to-day. In some seventeen or eighteen states registration is effected through an examination only, Massachusetts, North Carolina, Mississippi, and practically New York, Pennsylvania and California are in the list. The consideration and acceptance of credentials issued by another state board or foreign country, irrespective of reciprocity, is a method of registration in several states. New Jersey and Connecticut may be cited as examples. The third system is the reciprocating system, the I-will-if-you-will system, which has been adopted by thirteen or fourteen states. Maine, Vermont, Michigan, Wyoming and Oregon are examples. It is against this I-will-if-you-will system that this paper is specially directed.

---

* An address delivered before the National Confederation of State Licensing and Examining Medical Boards, Boston, June 4, 1906.

MEDICAL PRACTICE LAWS.

For a moment let us consider the basic principle on which all state laws relating to the practice of medicine are constructed. Justice Field, of the United States Supreme Court, in rendering an opinion of the full bench on a question raised as to the constitutionality of such legislation, says:

> The power of the state to provide for the general welfare of its people, authorizes it to prescribe all such regulations as in its judgment will secure, or tend to secure, its people against the consequences of ignorance and incapacity. . . . Due consideration, therefore, for the protection of society may well induce a state to exclude from the practice of medicine those who . . . are found, on examination, not to be fully qualified.

This opinion by the highest court in the country is authoritative. It declares that protection of society underlies state medical legislation everywhere in this country. The fact that, to be constitutional, medical legislation must be based on the necessities of society for protection against certain real or supposed evils, should be kept constantly in mind in discussing interstate reciprocity.

In 1894 Massachusetts enacted a medical practice bill which, with a few modifications, is the law of the state to-day. When this bill was under discussion the only argument of influence advanced in its favor was the need of such a law to safeguard the people of the commonwealth, as far as possible, against the charlatan and the incompetent, whose methods and practices constituted an evil amounting to a real menace to the well-being of society. Not a word was said that such a law would in the least benefit or enhance the convenience of practitioners of medicine. Such a suggestion might have proved disastrous.

The outcome of this effort to secure medical legislation was the stablishment of a state commission to determine the qualifications of applicants, irrespective of college diploma or certificates of registration issued by other states. Should an advocate of reciprocity petition the legislature now for an amendment to this law, providing for the admission of physicians to practice in this commonwealth by virtue of certificates of registration granted by other states, the question would be raised at once as to what or whose interests would be promoted by the enactment of such a bill? The petitioner of necessity would reply that such an amendment would make itinerancy easy, that it would facilitate the advent into this state of physicians from other states looking for new fields for practice, inasmuch as they would not be called on to submit to examination tests as to their qualifications. Such amendatory legislation would admit to the ranks of the profession in this state persons adjudged qualified to practice by educational standards inother states, some of which at least may well be considered inferior to our own.

Should access to practice in any state be made thus easy? Is scarcity of physicians one of the evils confronting the people in any state to-day? If so, all restrictions on the importation of foreign talent should be removed and no scrutinizing tests applied. Rather than to advocate such a procedure of medical licensure, would it not be wiser and better to endeavor to limit the supply of practitioners, if possible, through efforts to achieve still higher standards in the medical school and in the licensing board in order that the men and women and children throughout all the states may be better protected in life and health and comfort by being brought into closer contact with a higher order of intelligence and skill in the medical profession?

It surely rests with the advocate of free interchange of registration certificates, call it reciprocity if you please, before his cause should receive recognition, to demonstrate how such a process of medical registration will best secure, or best tend to secure, the people of any state "against the consequences of ignorance and incapacity." The highest court in the land has said that considerations looking to the protection of society are the only considerations which enable a state to prescribe regulations to exclude from, or to admit any one to, the practice of medicine.

OBJECTIONS TO SO-CALLED RECIPROCITY.

At the risk of repeating myself somewhat, I desire to look at this matter from the standpoint of state regulations providing for reciprocity.

It Confers Exclusive Privileges on Certain Persons.—I contend that such regulations or statutory provisions as established in Maine, for instance, and in a number of other states, in effect confer exclusive privileges on certain persons. It must be clear to every one that the provisions of the Maine law discriminate against the citizens of that state and in favor of citizens of other states. Residents of Maine, young men of undoubted character and education, graduates of the Maine Medical School, applying for license to practice, are required to submit to a test examination by the Maine board; but young men residing in Tennessee, for instance, graduates of some one of the inferior medical schools in that state and registered there through the leniency of the examining board, would not be so required. Such a method of registration on the part of Maine surely constitutes a marked discrimination against the citizens of that state and, therefore, contravenes the provisions of the Maine state constitution.

It avails nothing to say that the applicant from abroad has taken one examination in his home state. Be that true, it may have been an examination equivalent, or not, to the usual examination tests in the state in which he seeks a license. If not equivalent, as likely not to be, the registration of physicians of low grade results. I contend that few states, if any, can afford to assume such a risk, lest they encourage thereby lower educational standards in the medical schools and in the profession generally.

Again, if reciprocity is to prevail to any great extent, it should prevail to the fullest. It should apply to all registered practitioners in the reciprocating states, irrespective of time or manner of registration; otherwise we would have class legislation, laws discriminating in favor of some and against others in the same line of business. This point, which, I think, is well taken, is ably presented by Dr. Beverly D. Harison,[1] the secretary of the Michigan examining board and a warm advocate of interstate reciprocity. He maintains that reciprocity, to be constitutional and of value to the profession (he does not say to the public), should include nearly the entire list of registered practitioners. He says:

---

[1] Harison, Beverly D.: THE JOURNAL A. M. A., August 13, 1904, p. 482; also Medical Record, Oct. 4, 1902, page 525; also Bulletin of the Academy of Medicine, October, 1905.

> Reciprocal legislation which provides only for the present and future practitioner, and ignores the older and experienced practitioner, for the reason that the latter has not obtained his license through a state board examination, is not only irrelevant and unjust, but is also unconstitutional.

Dr. Harison is consistent in the position he has taken. His is the only kind of reciprocity that would be just to the profession. But how many practitioners are there in any state ready to advocate such a far-reaching scheme, which is neither more nor less than an open door to admit to practice in any state any outsider without imposing any important restrictions whatever, except his ability to pay a registration fee.

2. It Deteriorates the Standard of Medical Education.—I assume that all the states are in favor of maintaining high standards of excellence in the profession. But under reciprocity, limited or unlimited, high standards, it seems to me, can not be maintained. How can a pond rise higher than its source of supply? Under reciprocity the standard of qualifications for practice in Pennsylvania, for instance, would fall practically to the level of the standards maintained in the reciprocating states, from which, in part, it would draw its supply of practitioners. I wish to be clearly understood on this point, because it is one of great importance to the public, in whose interests state commissions are established and, from year to year, are upheld.

One of the bulletins of the Academy of Medicine, published in 1904, contains much interesting and important statistical matter relating to the work of examining boards in 1903 in the several states. Similar statistics for the year 1904 were published in THE JOURNAL of the American Medical Association.[2] These statistics show the number examined in the different states and the percentages of successful and non-successful applicants. It is a matter of interest to note that these percentages are practically the same for each state for the years covered by the statistics, a fact which tends to show that the different states have fixed standards of qualifications to which from year to year they adhere with marked uniformity.

In 1904 Pennsylvania reported the examination of 581 applicants, of whom 20.8 per cent. failed; Connecticut reported 93 applicants examined, of whom 28 per cent. failed; California reported 296 examined, of whom 20 per cent. failed; New Jersey, 96 applicants, of whom 20.8 per cent. failed; Maryland, 187 examinations, 35.3 per cent. failures; Virginia, 175 examinations, 30.8 per cent. failures; Massachusetts reported 330 graduates examined, of whom 94 were from the Harvard Medical School. The percentage of failures for the year was 18.5 per cent.

By the side of this list place the following: Illinois reported 762 examinations, with 4.5 per cent. failures; Nebraska, 100 examinations, 7 per cent. failures; Ohio, 249 examinations, 5.2 per cent. failures; Georgia, 114 examinations, 3.5 per cent. failures; Michigan reported 53 examinations, with only 1.9 per cent. failures; Vermont, 55 examinations, 1.8 per cent. failures.

With such a showing of inequality in examination results in the states quoted, how can any one for a moment harbor the opinion that interstate reciprocity is practicable? Can Pennsylvania, drawing largely its supply of applicants for licensure from its excellent medical schools in Philadelphia, afford to fraternize with Illinois in a fee interchange of license certificates? By what subtle mental process is the conclusion reached that 4.5 per cent. of failures in one state is an exact measurement of 20.8 per cent. in the other? Does the difference of 16.3 per cent. of failures represent the superiority of the applicants in Illinois over those in Pennsylvania? Is it not more reasonable to conclude that the difference in percentages so uniform from year to year in the two states represents pretty closely the difference in examination methods and requirements? That the difference is due to the examiners, not to the applicants examined? But reciprocity, it is said, is based on equality of qualifications established by the examining boards in the reciprocating states.

In the published proceedings of the sixteenth annual meeting of American medical colleges, held recently, a distinguished member[3] of the profession is reported as saying:

> The primary object of the legislature is to supply qualified medical practitioners to the people, and that is always the object that the boards must have in view.

Truly and wisely said. But that is just what the advocates of reciprocity never have in view. The fact that such is the primary object of the legislature in every state in the Union in creating examining boards is the keynote reason why under existing conditions in this country interstate reciprocity is impracticable.

All moving bodies, animate as well as inanimate, follow the lines of least resistance. A wife in New York tires of her marital relations and longs for the freedom of single blessedness. She does not apply in the courts in that state for a decree of freedom. She would meet with too much resistance there; she equips herself for a few months residence in one of the Dakotas where she accomplishes her purpose and returns to New York a single woman. Here Dakota dominates New York. A young man in Connecticut is inspired with the desire for a medical education. He, too, follows the lines of least resistance and enters a weak school in Tennessee or Maryland. In due time he receives his diploma and is ready, he thinks, for practice. He desires to live his life in the practice of medicine in his native state, but he finds in Connecticut too much resistance in the examining board. So by force of circumstances he seeks and finds recognition as a practitioner in some other state whose laws and methods of registration are less stringent. In due time he returns to his native state with clean papers. Under reciprocity he is enrolled as a qualified practitioner. By such a method of registration, high educational standards disappear both in the examining board and in the medical school. Reciprocity levels down, never up. Logically considered, no other conclusion can be arrived at. Under reciprocity, states whose laws and requirements for registration are most lax dominate all the other states.

Last March, and again last month, two young men, last year graduates, one from a Baltimore school and the other from a Boston college, were before the Massachusetts board. In their last examinations the average rating of each, as returned by the examiners, was less than 65 per cent. and yet since their first failure in Massachusetts last March, both of these young men have successfully taken the board examination in another state and have received their certificates of registration. Under reciprocity, Massachusetts would be asked to admit these parties to practice, notwithstanding its state board had twice refused them recognition on the ground of incompetency. What can be said to illustrate more forcibly the impracticability of interstate reciprocity?

---

[2] Vol. xliv, May 6, 1905.

[3] B. D. Harison of Michigan.

The rating of examination papers is not an exact science, and from the nature of the work can never become so. A required general average of 75 per cent. for a successful examination means nothing whatever to any one, or to any examining board, other than the board establishing such percentage, as its starting and finishing point in working out its conclusions as to an applicant's capabilities to practice. It is an arbitrary requirement which might just as well be fixed at 65, 70 or 80 per cent. as at 75. "It is not the thing itself, but the way it is looked at that gives delight."

3. *It is of Limited Usefulness.*—Again, were interstate reciprocity universal among all the states and territories in the United States, its utility would not apply to more than one-half of one per cent. of the practitioners in the country who have been in practice for a period of not less than three years; and fully 90 per cent. of that one-half of one per cent. would include only the unsuccessful, the poorly equipped, the indolent members of the profession who are ever on the move looking for more productive fields in which to labor.

The medical profession is not a caravan on wheels. The call to the successful practitioner is not to move on, but to remain a fixture in the state and locality where he has earned a reputation and a merited recognition and where his usefulness is appreciated. To him reciprocity does not appeal. But we are told that there are "experienced and notable men in the profession, professors and teachers in medical colleges," to whom, in case they should need to change their state citizenship, reciprocity would be a "deserving and relieving measure." This is probably true, but such instances are very infrequent and too unimportant to the general welfare of the community to require special legislation in their behalf. Moreover, many examining boards have, and all should have, discretionary powers bearing on the examination and registration of such applicants. Their way into the ranks of the profession within the jurisdiction of any board, can be and should be made easier and more inviting than the course of procedure afforded by reciprocity.

4. *It is Impracticable Because of State Sovereignty.*—We are told by the advocates of reciprocity that registration laws put a "restraint on individual freedom guaranteed by the Constitution of the United States," that state boundaries are imaginary lines, and that physicians are not permitted to cross state lines to relieve human suffering. Were such statements true, reciprocity would not relieve the situation, for reciprocity is a method of registration, however undesirable. If they mean anything, they mean that there should be no legislation whatever regarding medical practice. The statement regarding the curtailment of individual freedom guaranteed by the Constitution, is a "glittering generality," thrown in the face of numerous decisions of the Supreme Court. Again, the registration laws in nearly every state in the Union provide for over-the-border practice by physicians residing in border towns. This class of practitioners is not calling for reciprocity.

Bearing on the impracticability of interstate reciprocity, much might be said on differences of legislation on medical matters in the different states; that in regard to skilled labor, professional work of all kinds other than medical, such as teaching, plumbing, engineering, or any other business conducted under a state license, or civil service regulations, reciprocity among the states is unknown. Each state is ever intent on the welfare of its own inhabitants. It sets its own standards for every department of endeavor and adheres to them with a spirit of enlightened state pride. On such matters the congress of the United States has no voice or control. The several states, under the Constitution of the general government, being left to themselves as independent judges on all such matters, it happens that wide differences of opinion on most subjects of legislation exist, which opinions find expression in law.

In matters medical I see no good reason why we should advocate interstate reciprocity between Maine and Connecticut, any more than between Maine and Canada. Canada, it is true, is a province of Great Britain, but the English parliament exercises no authority over Canadian practitioners, because Canada enjoys the privilege of legislating for itself in respect to its domestic affairs, just as each of our states is privileged by our general government.

Advocates of reciprocity are wont to refer to the fact that a license to practice granted by Great Britain, enables one to practice in any part of the United Kingdom, without being called on to submit a second time to an examining board test. But this fact does not help their cause in the least. The government of Great Britain and Ireland is monarchical; that of the United States is republican. One legislative body, the English parliament, enacts laws for the entire kingdom. In the United States there are fifty legislative bodies, each a parliament, so to speak, making laws for its own independent body of people, on all matters relating to its domestic affairs. A stranger entering the jurisdiction of the English government, for the purpose of practicing medicine, must prove his qualifications as required by the laws of that parliament. And this is the exact status of affairs in each of the sovereign states in this country. Interstate reciprocity therefore, receives no encouragement in an appeal to English methods of dealing with medical practitioners.

The spirit of commercialism enters to such an extent into the trades and professions everywhere, and incompetency and deception manifest themselves in so many ways detrimental to the safety and happiness of individuals and communities, the states have found it necessary to place restrictions on, or limitations to, almost everything from the preaching of the gospel down to the running of an automobile in the public streets. This they do not only to conserve, but to enhance public interests, to keep open the avenues of progress in science and art. Thus it happens that we meet on every hand, restrictions and prohibitions, as well as permissions and choice of action.

The practice of medicine without a license is a prohibition in all the states, and the conditions on which such a license can be granted, are fixed by law. Each state has its conditions, laws and ideals. Let each state adhere to its own. It has ever been the spirit of the old commonwealth of Massachusetts to maintain high standards in all lines of its endeavor, especially in regard to its educational institutions. Ever aiming at the highest, it desires to accept none that are inferior. As members of this organization, men and physicians, inspired by broad philanthropic purposes, let us cling to high ideals of professional achievement, usefulness and dignity.

ENTRANCE REQUIREMENTS.*

GEORGE W. WEBSTER, M.D.
Chairman of Committee on Entrance Requirements, Vice-President National Confederation of State Medical Examining and Licensing Boards, President Illinois State Board of Health.
CHICAGO.

At the annual meeting of this confederation at Atlantic City, June, 1904, I had the honor to submit a standard curriculum for medical colleges and to suggest in connection therewith that the entrance requirement should be the following:

(a) Seven years in the primary or grammar school.

(b) Four years of high school, preference being given to the scientific rather than the literary course.

(c) A special course of two years in chemistry, physics, biology and languages; or, a college course in which the last two years shall have been modified to meet the demands of the medical student.

This standard of preliminary entrance requirements was not adopted, but the committee was instructed to make a report at this meeting of the confederation. In the report, among other things, I said:

> The idealism of the German university maintains that the object and aim of an education is to develop in a symmetrical manner the mental faculties, to enable one to live to the utmost, to enjoy being. It is a doctrine of being, rather than of doing, of idealism rather than of realism, of the theoretical rather than the practical.
>
> On the other hand, there is a very large class who insist in the social, and more especially the economic, utility of all human actions. They believe in the practical, the utilitarian, that which produces immediate results. They want men who do things.
>
> The former argue that a man should devote 7, 4, 4, 4, 2 = 21 years of the best of his life to acquiring an education. Such a man, if he was always well, enjoyed good health in childhood, missed no time at school, and took no time for travel, would be ready to begin to earn his first fee at twenty-seven or twenty-eight years of age.
>
> A system of education which demands that a man shall spend twenty-eight or thirty years of his life in preparation for active participation in its duties, that he earn his first fee at even twenty-five or twenty-eight years of age, seems in this eminently practical age, and as measured by organized society, to be impracticable and impossible.
>
> Even in the so-called reputable medical colleges, there is nothing which approaches agreement as to the entrance requirements to be enforced, and in many of the medical colleges, these requirements are something fearfully and wonderfully made.
>
> Unfortunately, the question in the past has been, *not* what constitutes the very best preparation for the very best kind of life work, but, Where can I get the largest number of degrees with the least work, the least expenditure of time, and a minimum of expense?
>
> We should determine, as far as we may, what constitutes the ideal medical course, and then what kind of foundation such a course should have; in other words, the character of the preliminary training.
>
> Educators in general have given insufficient attention to the special requirements demanded by the student desiring to enter medicine as a career, and have not done their duty in aiding the trend of special mental development necessary to the successful practice of medicine.
>
> In this country there is an unmistakable rift between studies for culture and studies for vocation. The college course is pursued for culture rather than as a preparation for the professions.
>
> I believe that the liberal arts degree has, in a sense, at least, determined our educational standard; that it is the mark of the well educated man, irrespective of his calling, and that for those who are considering merely technical training rather than culture, there should be at least one year added to the medical course, a connecting link, and at present a weak one, between the high school and the medical school, and consisting of physics, chemistry, general biology, Latin and German or French, or both. Possibly the plan suggested by President Butler, of Columbia, would be even better than this. He says: "There should be a *college* course of two years in length, carefully constructed as a thing by itself, and not merely the first part of a three-year or four-year course, which will enable intending professional students to spend this time as advantageously as possible in purely liberal studies.

PRESENT CONDITIONS.

At the present time we are confronted by the following facts:

First.—The medical curriculum of the Philadelphia Medical College, founded in 1766, consisted of two courses of lectures of about sixty hours each, one in anatomy by Dr. Shippen, the other in medicine by Dr. Morgan. This curriculum has been gradually enlarged until to-day it contains a list of twenty-three subjects and the hours of instruction have been increased from a total of 120 to a total of about 4,000, the instruction extending over a period of four years.

Second.—In that same medical school, the entrance requirements decided on by the resolution of the trustees, May 27, 1767, were as follows:

> 1. It shall be required that such students as have not taken a degree in any college shall, before admission to a degree in physics, satisfy the trustees and professors of the college concerning their knowledge in the Latin tongue, and such branches of mathematics and natural and experimental philosophy as shall be judged requisite to a medical education.[1]

One of the four propositions quickly agreed on at the first meeting of what afterward became the American Medical Association in New York in 1846 was that "It is desirable that young men being received as students of medicine should have acquired a suitable preliminary education."

Third.—Notwithstanding the improved standards in the medical curriculum, little that is creditable in the way of raising the entrance requirements has been done by the majority of the medical colleges of the United States. In many instances they are lower than in the Philadelphia Medical College one hundred and forty years ago. Pedagogically and from the standpoint of the needs and rights of the people, the weak spot in our medical educational plan is that of entrance requirements. They are too slow and the medical colleges themselves are permitted to pass on their character. Even the entrance requirement of a high school is too low.

Fourth.—On the other hand, the greatly increased demands of the medical colleges make a college course of four years a longer time than the future physician needs to spend, in preparation for his medical studies. The report of the Associated Harvard Clubs, page 8. 1905, says:

> European experience all indicates that where secondary schools are highly organized and well conducted, and professional education amply developed, four years of liberal study can not be maintained between the school period and the period of professional study.

Again, in their report of May 26, 1906, page 8, the committee says:

> Even a cursory examination of the discussions on this subject discloses the fact that there is practical unanimity in this conclusion: That the period of four years between the second-

---

1. Packard's "History of Medicine in the United States," p. 199.

ary and the professional schools is too long and that the requirement for the four years' course for the A. B. degree, if continued, will result in the exclusion of the holders of that degree from the so-called 'learned professions.' The four years' course is doomed. Indeed, it is already disappearing through natural causes, the effects of which can not be avoided to the extent of saving or restoring the four years' course.

Fifth.—The mass of the poorer or even middle class medical colleges will adopt no higher standard of entrance requirements than those imposed by the examining boards. This question of entrance requirements will never be solved by the medical colleges and the medical associations, partly for pecuniary reasons, and partly because the college associations persist in going about it in the wrong way. For example, the president of the Association of American Medical Colleges, in his annual address at the meeting at Pittsburg, Pa., March 19, 1906, still harps on that constitutional impossibility, a national board, as the panacea for all our medical educational ills. He says:

> The inconsistencies of many of our state laws controlling the practice of medicine and surgery lead us to a demand for national laws that would abrogate the present irregularities and bring about a uniform educational standard, acceptable to every examining and licensing board in the United States. To further this end, I solicit the indorsement of this association that such a national board be created from delegates sent from each state and territory.

It seems unnecessary, and in this body it is unnecessary to repeat that everything relating to the whole subject of medical education, including preliminary entrance requirements, the license and control of the practice of medicine, belongs to the state; its regulation and control is an exercise of the general "police power" of the state; it is one of the state's rights with which the federal government has nothing whatever to do.

The state board of health, or the examining or licensing board in each state, is, in view of the authority vested in it by the legislature, the only body authorized to determine the condition or terms under which physicians are licensed to practice in that state. This body determines the character of the entrance requirements, the length and character of the medical course, the subjects embraced in the medical curriculum, the time to be devoted to each, the character and scope of the examination, the equipment of the medical college in order to be in "good standing" with the board. The state alone, each for itself, through its examining board, has the sole right to establish and to maintain medical educational standards.

ATTITUDE OF EXAMINING AND LICENSING BOARDS.

Clothed with the power and charged with the duty of establishing, maintaining and enforcing reasonably high educational standards in the interests of higher education and of the rights of the people, what are we as examining and lincensing boards going to do in regard to this all important question of entrance requirements? Are we going to do as has been done in the past, wait, and "play safety" and progress no faster and no farther than we are forced by popular demand, or are we going to accept the other alternative, that of leadership, recognizing an educational and public need before it becomes a demand, perceiving the signs of the times, interpreting correctly "the handwriting on the wall," acting vigorously and fearlessly in the right as we see the right, in the strength of a faith which we feel sure will be justified by future results. Something should be done and done soon. The only question is, shall we act, here and now, or shall we wait and act in harmony with the organized profession, of the American Medical Association through its Council on Medical Education. It is for you to decide.

MINIMUM ENTRANCE REQUIREMENT.

We believe, and therefore recommend, that the following should be adopted as the minimum preliminary entrance requirement[2] to the study of medicine. We also recommend that the confederation work in harmony with the Council on Medical Education of the American Medical Association, the American Confederation, the Association of American Medical Colleges and all committees and organizations of all legally authorized schools of practice.

1. A high school diploma from a recognized high school, or its equivalent in the form of a certificate showing that the applicant has passed a satisfactory examination in all the branches usually embraced in the curriculum of a four-year high school course, said certificate to be either issued or passed on by some designated state official, such as the superintendent of public instruction, and not by any one connected with any medical college.
2. Satisfactory documentary evidence of having completed at least one year of not less than nine months' of work in chemistry, biology, physics and languages in either a recognized institution of learning chartered to confer liberal degrees, or in a recognized medical college, having a special additional year devoted exclusively to the above subjects, this requirement to apply to all students matriculating after Jan. 1, 1910.

In the foregoing I have used the term "year of work." Following the important suggestion made by Dr. B. D. Harison, secretary of the Michigan Board of Examiners, something should be done to improve and render uniform our terminology in describing and defining work. As I understand it, the following terms are in use. The term "count" is used by New York, meaning one hour each week of class room work throughout the college year. The term "point" is used by the Association of American Medical Colleges, meaning thereby two recitations each week throughout the college year. The term "course" is used at Harvard, meaning three hours each week. The term "unit" is used by the Michigan board and by the Michigan university and means four hours each week throughout the year. To recapitulate: "Count" equals one hour each week; "point," two hours each week; "course," three hours each week and "unit" four hours each week. All mean a certain definite number of hours. Then why not say so. But if any term other than the word "hour" or "hours" is used, let it be the New York "count" because of its age and simplicity.

THE TREATMENT OF EMACIATION.*

L. BREISACHER, M.D.
Professor of Clinical Gastroenterology, Detroit Medical College; Consulting Gastroenterologist, Harper Hospital.
DETROIT.

Almost daily, persons consult me whose one great sorrow in life is their condition of leanness or emaciation. They come to me with the request that I make them fat and plump.

A few of these persons are actuated in their request by the knowledge that their bodily strength and resistance have suffered as the result of their abnormal weight reduction. Others again recognize that their leanness is the expression of some digestive or metabolic disorder. With the great majority of persons, however, these matters are left out of consideration, their sole desire in wishing to become fat being to improve their personal appearance. The first writers who ventured on the subject of the treatment of leanness recommended that the individual be liberally fed, and with this advice we are indeed in the fullest accord, but, like almost all writers up to the present time, they have ignored the causes and the accompanying conditions of this difficulty.

---

[2] This standard was unanimously adopted at the Boston meeting, June 4, 1906, and by the Illinois State Board of Health, June 20, 1906.

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Chapter on chapter has been written by dietitians on food values, fat producing foods, the possibility or impossibility of forced albumin feeding, etc., in reference to the treatment of leanness, but the underlying causes and a thorough consideration of the digestive and absorptive factors as well as the significance of medical treatment, have been entirely ignored.

CAUSES.

Leanness may be the result of various causes. It may be of an apparently hereditary character, or it may be acquired and arise as a primary or secondary condition. The one great cause of leanness excluding diseases like tuberculosis, diabetes, nephritis, and cancer and conditions like stenosis and vomiting, is the ingestion of an insufficient amount of food. This may result from a primary or secondary loss of appetite or a repugnance to food in consequence of various disorders, or as the result of emotions like pain, grief, sorrow, etc. It may be the result of faulty dietetic habit which I have seen handed down through several generations in a number of families.

Frequently it results from an ignorance of the nutritive significance of particular foods, or from the effect of eating but one or two meals a day by persons not constitutionally fitted for that sort of régime. It may be the result of poverty or the attempt to economize. It may be due to sexual neurasthenia, hysteria and nervousness, especially in persons of a typically nervous temperament.

These latter causes together with digestive abnormalities have formed the basis of the great majority of cases of emaciation which have come under my observation. In an interesting paper, recently published, Cabot mentions arteriosclerosis and sleeplessness, which latter condition I have often noticed, at least as an accompaniment of other symptoms, in a number of my cases.

To the second group of causes belong the gastrointestinal disorders which may be either of mechanical, chemical or secretory origin. I have observed them as a primary or secondary cause in almost all of my cases. There is no doubt whatever that the foundation of this class of diseases, with the frequently resulting emaciation, is often laid at the time of the birth of the child when it is artificially instead of naturally fed. We may further add to this list of diseases producing leanness all the circumstances in general which produce digestive disturbances.

As causative agents in the production of leanness, I might also mention the improper metabolism of food and the increased oxidation of food after it has become an integral part of the blood. We can not define these conditions, however, with any degree of precision, and it is not our object in this place to enter into a speculative consideration as to the possible nature of these conditions.

It will thus be seen that many circumstances and conditions, either singly or combined, may operate in the production of leanness. Cases may belong to that class which we may ascribe to hereditary influence, and which result from habitual underfeeding which I have noticed in successive generations of different families; cases of apparently simple or primary leanness may, on examination, be found to rest on some undoubted physical or nervous basis.

TREATMENT.

In the treatment of this condition it behooves us, therefore, to examine our patient thoroughly, and an examination is incomplete unless the state and degree of digestive activity have been accurately determined. One should know to what degree the stomach and bowels will bear forced feeding and what foods these organs will most readily digest and absorb. The selection of the kind and quantity of food and the determination of the quantity of liquids depend on these examinations.

With the absorptive and digestive activity of the stomach determined, and all other possible causes considered, I map out a diet list which will contain from 2,200 to 2,500 calories and gradually increase the amount until I reach a diet containing from 3,800 to 4,500 calories.

I strive to give from 100 to 250 gm. of fat in the form of milk, cream, butter, olive oil or emulsion; 100 gm. of fat equal 930 calories, 250 gm. equal 2,325 calories, If we add sufficient albumin containing food to amount to 150 gm. and carbohydrates amounting to 400 gm., the caloric value will be increased to 615 and 1,640, the entire caloric worth amounting to 4,580 calories. Thus:

Fat	250	×	9.3	=	2,325
Albumen	150	×	4.1	=	615
Carbohydrates	400	×	4.1	=	1,640
					4,580

The question as to how much or how little albumin is to be selected and the nutritive value of the different naturally and artificially digested foods I have discussed in former publications and need not repeat in this article.[1]

I always resort to tonics, both vegetable and mineral, given either hypodermically or by the mouth, and, when the occasion demands, I push them to their physiologic limit. In nervous individuals, I always use nerve sedatives, never of course resorting to narcotics of any kind. The medicinal list includes iron, arsenic, gold, manganese, strychnin, gentian, cinchona, quinin, condurangó, colombo, sumbul, bromid and valerian. I always resort to the tonic, reconstructive, stimulative and sedative, actions of these drugs, which, when combined with properly selected foodstuffs, determine the outcome of the case.

From time to time I estimate the excretory activity of the kidneys, and compare it with the entire water intake, which should be from 2,000 to 3,000 c.c. I lessen or increase the exercise as the case may require, and resort to frequent tepid baths, cold rubs, massage and electricity. On a régime of this kind, convalescents often gain weight so rapidly that it becomes necessary to reduce the diet. The chronically underfed usually require from two to six months of very careful manipulation with the continuous coaxing of the digestive tract, and the constant tempting of the palate to achieve the desired result. Not only for an esthetic effect, but also as a prophylactic and curative means, the logical fattening of individuals is of an importance which can hardly be overestimated.

MUCOID SALTS.*

WILLIAM J. GIES.
NEW YORK CITY.

We know practically nothing about the ways in which proteins are held in living protoplasmic structures. The molecules of the protein compounds are relatively so large that as yet our physicochemical methods of measurement are inadequate to give us correct ideas of molecular size and intramolecular structure, although we know considerable about the lifeless and, in some respects, comparatively meaningless fragments into which protein molecules may be broken. Our ignorance of the fundamental biochemic relations of proteins to the associated constituents of protoplasm appears to be largely due to our vague knowledge of the chemical statics and dynamics of true cellular proteins, a fact which serves as a constant stimulus to protein investigation.

Among the many protein substances the nucleoproteins and the glucoproteins are very important tissue constituents. The essential part of each natural type of these proteins, and the part to which the usual name is applied, appears to be a colloidal organic acid. The forms in which the acid radicals occur in cells and tissues have not been definitely made out, although it is natural to presume that the acid radicals are united directly to one or more distinctly basic radicals in each case, and that variations in the characters of such compounds are associated with physiologic as well as pathologic variations of cellular composition and tissue function.

I have endeavored to get to the bottom of this complicated matter, by making definite salts of these proteins with the aid of methods that could be relied on to leave the acid radicals unchanged. In this effort I have been encouraged by the hope that, by increasing our knowledge of artificial products, analogies with natural compounds would be not only more easily recognized, but also the characters and functions of the compounds in living protoplasm would be more thoroughly understood. Thus, at present, it is impossible to recognize satisfactorily the form or forms in which mucoid is contained in the connective tissues under either physiologic or pathologic conditions, nor are we able to explain, for example, the possible relationships of spermatic protamin (basic) and ovular mucoid (acid) to the more differentiated mucoid (acid) so conspicuous in embryonic tissue. I believe that a study of artificial products of such types as those referred to, will make it possible successfully to elucidate numerous problems awaiting solution, many of which my co-workers and myself have under investigation.

About five years ago I found that "when the electric current is passed through neutral or alkalin mucoid solutions (consisting of sodium or calcium salts of mucoids) turbidity results within a short time and flocks eventually form and can be filtered off." This observation was included in a preliminary report of work then in progress.[1] About the same time Huiskamp[2] had been making similar observations in connection with nucleoprotein salts from thymus. Shortly afterward, in preparing material for work in another connection, I[3] precipitated from an alkalin solution (Na_2CO_3) of mucoid with the aid of acetone, after failure with alcohol, a water-soluble compound, apparently sodium mucoid. This fact has not been published hitherto, although it was stated at that time that organic compounds such as gelatomucoid had been obtained.[4]

I have lately prepared calcium, sodium, potassium and ammonium salts of mucoids by the following process: The glucoprotein was obtained in slightly alkalin solution. This solution was dialyzed until neutral and then was poured into a large excess of 95 per cent. alcohol, by which treatment the mucoid was immediately precipitated. Initial purification was effected by resolution, dialysis and reprecipitation. The products were rendered anhydrous by treatment with absolute alcohol and ether. Probably all bases yield such salts, although, for the present, I shall confine my remarks to the simple inorganic salts mentioned.

The comparatively pure inorganic salts of the mucoids already prepared are light, snow-white powders. They dissolve in water very readily and are dissociable products. The concentrated solutions resemble mucus. The aqueous solutions are neutral to litmus and acid to phenolphthalein. Ammonium compounds have been prepared that were acid to litmus also. The calcium salt yields about 12 per cent. of ash, whereas the corresponding mucoid is practically ash-free. It is very probable that the mucins in the secretions occur in the form of such salts, as Müller has already suggested. Yeast nucleoprotein has also yielded similar products. Presumably other nucleoproteins will be found to do so also.

I believe these observations clear the way for important discoveries connected with the glucoproteins, nucleoproteins, proteinates and similar protein products. The best method of preparing the compounds referred to has not yet been definitely ascertained, but I hope to describe it in detail at an early date.

EXPERIMENTAL CEREBROSPINAL MENINGITIS AND ITS SERUM TREATMENT.*

SIMON FLEXNER, M.D.
NEW YORK CITY.

Cerebrospinal meningitis prevailed as an epidemic in Greater New York City during the winter of 1904 and the spring of 1905. Since that time up to the present writing, sporadic cases of meningitis still arise. In the spring of 1905 the Health Department of New York City appointed a commission to co-operate with the department in investigating the epidemic. As a member of the commission I undertook an experimental investigation of meningitis out of which the preliminary report has grown. The full report of this investigation will appear in a forthcoming number of the *Journal of Experimental Medicine.*

---

* From the Rockefeller Institute for Medical Research, New York.

The bacteriologic examination of the exudates from the meninges, obtained by lumbar puncture and at autopsy, showed the epidemic to be caused by *Diplococcus intracellularis* of Weichselbaum. My work was done almost entirely with this micro-organism. The sources of my cultures were the following: Dr. E. K. Dunham, Dr. Martha Wollstein and Dr. E. P. Bernstein. From Dr. Dunham I obtained a large number of cultures which he isolated from cerebrospinal fluid and the nasal mucous membrane of patients; from Dr. Wollstein I obtained cultures isolated at the Babies' Hospital, and Dr. Bernstein supplied me with cultures from patients at Mt. Sinai Hospital. In a few instances I made my own isolations from freshly-drawn cerebrospinal fluid. The large number of cultures of the diplococcus, or similar organisms, which were examined could not all be tested on animals. The biologic characters of a larger number of cultures than could be tested for their pathogenicity were studied. *Diplococcus intracellularis* possesses biologic characters which permit of its identification with a high degree of certainty. The cultural appearances on the usual media, temperatures of development, actions on sugars and brief viability, under ordinary conditions, all tend to distinguish the intracellularis among the wide group of non-Gram-staining diplococci. The brief vitality of many cultures of the intracellularis is a point of high differential importance. Many strains, grown on a favorable medium, unless transplanted to a fresh medium, do not survive beyond two or three days. Indeed, these transplantations do not succeed, frequently, unless considerable quantities of the growth are carried to the fresh tubes, an indication that only a fraction of the cocci have survived, or are still capable of multiplication. Vigorous fresh cultures of 16 to 24 hours' growth stain sharply and uniformly. On the second day the cocci show irregularities in staining and size, unless they have been carefully preserved from evaporation and fluctuations of temperature. Cultures three days old show marked degenerations, and these increase rapidly with age until, at the end of five or six days, no normal cocci persist. Even with very careful preservation the great majority of the cocci do not survive beyond this brief period. A few cocci, in carefully preserved cultures, may survive for many months. The appearance of old cultures is characteristic. At the beginning of the degeneration swollen-deeply-stained cocci occur among the smaller but usual forms, which take the stain less intensely than fresh cultures. As degeneration progresses loss of nuclear-staining and disintegration occur, until, finally, staining power is entirely lost and a formless detritus remains.

If a vigorous culture of the diplococcus is suspended in 0.9 per cent. salt solution and the suspension is kept at 37 degrees C., the cocci slowly undergo the changes described. Since in such a fluid medium evaporation goes on slowly and alterations in concentration are consequently small, the cocci degenerate less rapidly than when grown on the surface of solid media. Finally, the salt suspension of cocci also degenerates. If, however, to such a salt suspension a few drops of toluol be added and mixed with the fluid by agitation, the process of disintegration is greatly accelerated. Such a suspension, kept at 37 degrees C., may be wholly disintegrated at the expiration of 24 hours. The conclusion which may be drawn from this observation is that *Diplococcus intracellularis* possesses a highly potent autolytic ferment which tends, once the cocci are dead, quickly to cause disintegration of the micro-organisms. I noticed repeatedly when I transplanted thick suspensions of old cultures to fresh media that the turbid fluid became clear after a few hours, indicating solution of the bacterial substance in the new fluid used to dilute the original growth. I made some comparisons of the rapidity and degree of disintegration of the cocci which take place when the salt suspensions of cocci are toluolized and occasionally agitated and when they are not killed outright, but are shaken continuously for several days. The disintegration is much more rapid and complete in the toluolized specimens. The autolytic ferment is destroyed by heating the suspensions to 65 degrees Centigrade.

This great susceptibility of *Diplococcus intracellularis* to changes in osmotic conditions, and possibly to variation in temperature and accumulation of products of growth, separates it from a large number of non-Gram diplococci of various origins. The slight vitality of the diplococcus is bound up with this susceptibility. I noted the fact, at the beginning of my experiments, that cultures placed on ice might be dead in less than 24 hours. Later I made a few experiments on the viability of the cocci in thick, salt solution suspensions kept in a refrigerator the temperature of which varied from 2 to 4 C. In this case many living cocci were still present at the end of five days.

I secured a considerable number of non-Gram diplococci from human beings and animals which differed from *Diplococcus intracellularis.* Some of the former came from the nasal cavity of persons, children chiefly, suffering from epidemic meningitis. Others came from healthy persons who had not been exposed to cases of meningitis. A few cultures of so-called *Micrococcus catarrhalis* were sent me by other bacteriologists. In connection with the investigation of the Department of Health I had my assistant, Mr. Ward, study a number of domestic pets—cats and dogs—obtained from the houses in which cases of meningitis occurred. Several of these animals yielded cultures of diplococci which were decolorized by Gram's staining method. An autopsy on a case of cerebrospinal meningitis, the child having died in the sixth week of the disease, yielded a non-Gram diplococcus which belonged to this group. A few colonies of the coccus were obtained from the bronchial lymph glands, lungs, antrum and medulla oblongata, the last being covered with a thick exudate. All these cultures differed from the examples of *Diplococcus intracellularis* in not tending to undergo the rapid degeneration and disintegration described for that organism. Associated with this difference were the further differences that they grew from the first on media to which blood in some form had not been added and were viable over a long period of time—often for many weeks. They were, further, either devoid of power to ferment sugars or they possessed wider or more vigorous fermentative powers than the intracellularis.

A toluolized salt solution suspension of *Diplococcus intracellularis* quickly disintegrates, as has been stated. This fluid, deprived of its toluol by evaporation at a low temperature, and centrifugalized at high speed to remove solid particles, is toxic. The toxic constituents pass through unglazed porcelain (Berkefeld filter). The toxic effect of this fluid can best be studied on young guinea-pigs. Selecting pigs of 125 grams weight or less for the test, the degree of toxicity will depend on the strength of the original suspension of cocci. If the entire growth on the flat surface of a one-pint Blake bottle be suspended in a 10 cubic centimeters of salt solution the lethal 18 to 24 hour dose given intraperitoneally will be from 0.5 to 1 cubic centimeter. The lesions which result are similar to those caused by injections of living suspensions of cocci, except that fibrin may not appear.

The activity of this extract can be shown in still another manner. Since Bail's work on aggressins, so-called, and Wassermann's and Citron's observations on extracts of bacteria in promoting infection, we have learned that the pathogenic effect of bacteria may be intensified by combining them with these products. Guinea-pigs which have been inoculated simultaneously with living cultures and the autolysate of the cocci succumb more certainly and are subject to smaller doses of cocci than animals given the cocci alone. Intraperitoneal injections of the diplococcus in guinea-pigs gives rise to the production of an exudate which exerts an action similar to this extract in promoting susceptibility to the coccus.

As tested on laboratory animals *Diplococcus intracellularis* is a micro-organism of low and variable pathogenic action. Small guinea-pigs are, I found, more useful than mice for studying the effects of the cultures. The difference in susceptibility of guinea-pigs, according to weight, is very large. Guinea-pigs of 175 to 200 grams weight proved highly susceptible to the cocci as compared with pigs of 350 to 400 grams weight. Pigs of 250 grams are still useful for these tests, while full-grown pigs are highly refractory.

Not all cultures of the diplococcus, even in the first generations, are pathogenic for the small pigs, unless, indeed, very large quantities be injected. Speaking generally freshly isolated cultures are pathogenic, while cultures grown for a period on artificial media are not. Occasionally a strain of the coccus will retain its pathogenicity for many months, but, as a rule, the power is lost after the first transplantations extending over a few weeks. I have worked with cultures which have deteriorated in a few days, and one culture (Smith) retained its power undiminished for many months, to lose it in the end. This culture was passed through many mice, guinea-pigs, and monkeys during its active period. but, after its activity was lost, it could not be restored by passage through mice and guinea-pigs. It still yields an active extract and can be used as an adjuvant to living cultures. No increase in power was produced by passing it through ten successive generations in a medium consisting of bouillon and serum of a goat immunized to the diplococcus.

The reaction to inoculation, in the guinea-pig, varies with the degree of pathogenic power possessed by the strains of the coccus. In my studies I found it necessary to adopt a standard strength of culture to be inoculated. It was not readily possible to obtain uniform growths on agar-serum surfaces; hence I prepared from the large flat surfaces a suspension in salt solution which had a uniform degree of turbidity. The suspensions should be made from freshly-grown cultures (preferably under 24 hours old) and used soon after preparation. It is unsafe to carry suspensions over until the next day, unless a new determination of their strength be made. Partial deterioration quickly sets in.

The standard dose of the suspension varied, as a rule, from 0.1 to 0.5 cubic centimeter, for the small pigs, by intraperitoneal inoculation, and death occurred in less than 24 hours. Active cultures, in this strength of suspension, may cause death, in the smallest dose given, in 8 to 10 hours. A culture which in a dose of 0.5 cubic centimeter requires 24 hours to kill is one of weak virulence. In the course of any large series of experiments irregularities occur. It has happened that a guinea-pig of a series died in 4 hours and another survived 36 hours. But these irregularities can be ruled out by making duplicate inoculations. Among survivals it happens occasionally that death takes place after several days and is preceded by a state of great emaciation.

The most important lesions exist in the peritoneal cavity. Excluding the two extremes (death in 4 hours or after several days) the appearances and conditions present are uniform. It is the rule for the pigs of a series to succumb in about the same period, within one or two hours of each other. Where the coccus causes death in 12 to 14 hours the results are likely to be very regular. Greater irregularities occur where death is delayed until 24 hours after inoculation.

Fluid exudates into the cavity of the peritoneum are the rule, and more or less fibrin and pus covers the anterior surface of the liver and is present in the rolled up omentum. In gross appearance there is not great distinction between the animals succumbing in 12 and in 24 hours. But microscopic examination shows the difference to be considerable. It is the virulent cocci which bring on the more rapid forms of death. The exudate in this case shows many, often prodigious, numbers of cocci. The appearances are indicative not only of preservation of the injected cocci, but are suggestive of their multiplication. In the case of the less virulent cocci, the exudate contains fewer micro-cocci and may be devoid of them. Even when death occurs in the short period mentioned, the number of cocci is likely to be small. In other words, virulence and resistance to destruction go hand in hand. A relatively non-virulent strain of coccus may still be toxic, but has little or no capacity to resist disintegration and none for multiplication in the peritoneum. Hence two appearances are met with between which transitions occur. When the strain of coccus is actively virulent multiplication in the body probably takes place, but in any case there is only slight dissolution of the injected micro-organisms, and cultures are positive. Death usually takes place early, and it is rarely that a more resistant pig survives beyond the usual period, and even then cocci are still present in numbers. When the strain of coccus is little virulent it tends from the beginning to disintegrate, and, even if the animal succumbs early, the peritoneal cavity may be devoid of micro-organisms, or, should a small number still be present, they often do not develop in cultures. The more virulent cocci invade the blood and tissues and can be cultivated from the blood, internal organs, bone marrow, etc.; the less virulent cocci are not found in the interior of the body.

I have made some observations on the strength of the toxic fluids yielded by different strains of cocci through autolysis, and they indicate that these fluids have not the same absolute strength. The more virulent cocci yield, at times, an autolysate of greater toxicity than the less virulent micro-organisms. In view of the adjuvanting effect of the autolysate it may well be that it is this potent toxic extract which makes the former cocci survive and multiply in the body, for a part of them undergoing dissolution could supply the necessary autolysate to reduce the resistance of the animal. In case of the cocci of small virulence, the lethal action is, according to this view, due wholly to the liberated endotoxin for which larger quantities and longer time are required.

I have made some experiments on the dissolving power of the peritoneal exudate, from guinea-pigs, on the diplococcus. The fluid exudate is removed and freed from cells by centrifugalization. It possesses high digestive powers for the cocci. Mixed with fresh cultures many of the cocci are killed and disintegrated, and the cocci in the mixture which has been toluolized undergo dissolution much more rapidly. Enormous numbers of cocci can be digested by the exudate, which is increased in toxicity thereby. The dissolution of the cocci in the toluolized exudate goes on much more rapidly than in salt solution. The exudate heated to 58° C. for from 30 minutes to one hour has the same digestive action as before on fresh cultures and on cultures heated to 65° Centigrade. It is, therefore, assumed that its action is enzymotic. The blood serum of the guinea-pig has not the power to digest the cocci.

A measure of the reaction of the guinea-pigs is found in the emigration of leucocytes. In the cases of rapid death with preservation of the cocci the emigration is slight or wholly absent, while in the cases of slower death and disappearance of cocci the emigration is considerable. Many transitions between these extremes exist. When emigration is at all marked, even with an almost entire preservation of the cocci, phagocytosis has taken place. Where there has been considerable, although not total, disappearance of cocci, phagocytosis is more abundant. Phagocytosis is a function of emigration, but it is not a measure of this condition. The disappearance of the cocci from the peritoneal cavity does not depend wholly on phagocytosis. I believe that the cocci may be removed without the intervention of phagocytosis, probably through self-digestive action and digestive action of the inflammatory exudate.

The leucocytes are numerous, frequently, in the omentum and every fibrinous exudate, while they are few in number in the peritoneal fluid. The clear peritoneal fluids contain few leucocytes relatively; the turbid fluids contain many. Since the turbid fluids occur in animals surviving the longer periods, there is relation between degree of virulence and emigration. But since the emigration is more abundant in those animals in which the cocci quickly disintegrate, it would not seem to be wholly called forth by the need for phagocytosis. The toxic extracts of the cocci cause fluid exudations into the peritoneal cavity, but not turbid ones, so far as I have seen. Possibly fragments of the bacterial bodies present in injections of cultures and absent from centrifugalized and filtered autolysates attract many leucocytes. The leucocytes of the omentum are large and pale, and those of the peritoneal fluid small and dense. Their nuclei are often irregular in form or fragmented. Cocci are common in the protoplasm and rare in the nuclei, and they show all transitions from well-preserved organisms to fragments and swollen, metachromatic bodies.

The main visceral lesions met with in the pigs are (1) vivid congestion or hemorrhages of the adrenal glands; (2) hemorrhages into the mesentery and central tendon of the diaphragm; (3) gelatinous edema of the pancreas and peripancreatic tissues.

At the beginning of this investigation I had the plan of using monkeys to reproduce the lesions and symptoms of cerebrospinal meningitis in man. Some of my earliest experiments were made on these animals. The cultures were introduced into the spinal canal by means of lumbar puncture. The injection was made commonly in the canal at the level of the third lumbar space. This space is not below the level of the cord in many monkeys, but I have never had paralysis follow my inoculations. My first experiments were successful in producing acute leptomeningitis from which the animals died. The symptoms in different animals were depression, coma, convulsions, nystagmus, opisthotonos, etc. The experience which I was obtaining with guinea-pigs was of much use to me in the work on monkeys. The variable virulence of the cocci affected, at the beginning, the successful experiments with monkeys, as it did with guinea-pigs. By choosing suitable strains of the coccus I succeeded in inducing severe and fatal leptomeningitis in a large number of monkeys. Through the use of lumbar puncture, in the course of the disease, I studied the manner of reaction of the animals and the fate of the micro-organisms. I shall give in this place the protocol of my first experiment on monkeys, since it represents a typical case.

Macacus nemestrinus, May 12, 1905, 10:30 a. m. A good-sized monkey was etherized,[1] after which a needle was introduced into the spinal canal; clear, watery fluid escaped from the needle. A culture eighteen hours old of the *Diplococcus intracellularis*, in its first generations, on Loeffler's serum, was injected. The culture consisted of many discrete colonies and had been suspended in 2 c.c. of salt solution. The monkey quickly recovered from the operation. Six hours later it appeared to be sick; at 6 p. m. it no longer sat on its perch; 9 p. m., still on bottom of cage; head down, appeared very sick; on being disturbed it moved slowly. Death during the night. Survived injection probably eighteen to twenty hours.

Autopsy, 9 a. m., May 13: The internal organs, except the nervous system, showed no striking lesions. Brain and cord: No marked excess of fluid in the meninges. Convex surface of the brain greatly congested, punctiform hemorrhages in the pia arachnoid and superficial portion of the cortex. No definite exudate on the convex surface of the convolutions, although the pia of the sulci appeared white and slightly thickened (probably an old condition). A focus of softening, or an abscess, the size of a large pea occurred to the right of the superior longitudinal sinus in the convolutions anterior to the motor area and just beneath the membranes. The base of the brain was covered with an opaque exudate, white in color, which extended over the medulla and anteriorly to the optic commissure. The lumbar and thoracic portions of the spinal cord were covered, posteriorly chiefly, with an opaque, white exudate. The diplococcus was recovered in cultures from the exudate of the spinal cord and base of brain and from the blood of the heart. Smear preparations from the exudates showed large numbers of polymorphonuclear leucocytes, many of which contained the diplococcus, and they showed diplococci lying free in the exudate, The softened focus contained masses of leucocytes and enormous numbers of the diplococci. The microscopic examination of sections of the inflamed brain and cord showed the existence of an acute fibrino-purulent exudate within the pia arachnoid and a superficial encephalitis.

By means of this and later experiments it was shown that the lower monkeys could be infected without great difficulty with *Diplococcus intracellularis* and made to reproduce the pathologic conditions present in man in epidemic cerebrospinal meningitis. The experiments proved that the cocci, when introduced into a low level of the spinal canal, would distribute themselves in a few hours through the meninges and excite an inflammation, the exudate of which accumulated chiefly in the spinal meninges and the meninges of the base of the brain. The uniformity with which the chief exudate was found at the base of the brain and the rarity of its appearance in considerable amounts over the convexity led me to doubt the validity of the reasoning which ascribed this localization in man to the entrance into the meninges of the infective agent directly through the nasal mucous membrane. This tendency to localization at the base of the brain in monkeys is especially interesting in view of the fact that it is usually only a short time before death that they lie down on the side. In comparing the experimental lesions in the monkey with the naturally developed lesions in man note should be taken of the occurrence, under both conditions, of encephalitis and of abscess formation, due to the invasion of the substance of the nervous tissue by the diplococcus.

---

[1] In later experiments ether was not used, since the operation gave little pain.

In contrast to the ease with which the acute inflammation can be excited is the difficulty which attends the production in the monkey of a subacute form of meningitis. The intraspinal injections produce either an acutely fatal meningitis or an acute disease from which recovery takes place rapidly. The animals which survive inoculation are usually well of the disease in three or four days. In rare instances the animal lingers a victim of the disease for a longer period than this to succumb in the end. Monkeys which survive the second day after inoculation tend rather to recover than to die. By following in inoculated animals the changes in the spinal canal by means of lumbar puncture, the progress of the infection can be traced and the final result often predicted. There is much similarity between the changes occurring in the spinal canal of monkeys and those in the peritoneum of guinea-pigs. The most striking difference is the greater degree of phagocytosis that takes place in the spinal canal, although the cocci are not all removed in this manner and the same difference in resistance to destruction, depending on virulence, is found in both animals.

Disappearance of cocci early from the spinal canal is a good sign; early emigration of leucocytes is also a good sign; early emigration, active phagocytosis and dissolution of the cocci, both within and without the leucocytes, are very favorable signs. And just as in the guinea-pig death may take place in spite of the entire disappearance of cocci from the peritoneum, the monkey may succumb, although cocci cannot be found either in smears or obtained in cultures from the inflamed membranes.

By following in this manner the results of inoculation I have been able to keep a small number of monkeys in a state of subinfection for several weeks with the diplococcus. The period of successive inoculating was determined by the puncture and by the physical condition of the monkey. A state of resistance tended to develop, which necessitated the use of increasing amounts of cultures to produce visible effects, and in the end the rundown animal succumbed—usually from an inoculation with an overdose of cocci. In these animals the exudates were thicker and firmer, and covered the base and convex surface of the brain. The ventricles were widely dilated and contained turbid exudate.

Although the pathologic effects produced in these monkeys are comparable to those occurring in the natural disease in man, there is no real correspondence in the relative susceptibility to *Diplococcus intracellularis.* The quantity of an active culture required to cause marked symptoms or bring about death from meningitis in monkeys is prodigious if compared with what probably happens in the human infection. Moreover, the amount of multiplication of the cocci in monkeys is, under the most favorable conditions, small, and I am disposed to think that in many of the experiments no multiplication whatever took place. In the case of abscess formation I believe multiplication of the cocci to occur. Experiments are in progress to determine to what extent the symptoms and lesions of meningitis can be produced by means of the soluble poison yielded by the cocci.

The inflammation of the meninges extends in monkeys into the membranes covering the olfactory lobes, and, as I have made out by means of smear preparations, into the ethmoid cells and into the nose. The nasal mucous membrane is found, in some instances, to be inflamed and beset with small hemorrhages. Smear preparations have shown me polymorphonuclear leucocytes, often in large numbers, carrying diplococci, which presented the form, size, staining qualities and degenerations of the cocci occurring in the same cases in the cerebral and spinal meninges. I failed in two attempts to cultivate the cocci from the nose, owing possibly to the extraneous bacteria present. On account of the bearing which the passage of the diplococci from the meninges into the nose would have on the epidemiology of meningitis, it is intended to repeat the effort at cultivation of the cocci from the nasal passages.

Notwithstanding theoretical discouragements, an investigation of the influence of antisera on the experimental infections with the diplococcus was undertaken. I assumed that the main pathologic phenomena played themselves out in the localities in which the cocci were injected, and hence as the sera could be brought directly into relation with the foci of infection, possibly a benign effect might be excreted.[2] I was influenced, too, by the consideration that in man the chief organic lesions of epidemic meningitis are present in the meninges, and appear only later, possibly, in the brain and cord, and in many cases the bacterial development is not very great. There was another consideration to be taken into account, for if the experimental disease in the monkey could be arrested by the injection of antisera into the spinal canal, and it proved that no ill effects followed the injections, the advisability of making similar injections might be thought of, possibly, even in human beings suffering from cerebrospinal meningitis.

The experiments with antisera, the results of which will be briefly given, were more satisfactory than I had expected they would be. They do not, however, represent conclusions, but merely the beginnings of an investigation into this important and difficult field of study.

The antisera were prepared in rabbits, goats and large monkeys. The rabbits were injected with single strains. the goats with many strains of cocci. The monkeys were injected with cocci and exudates (aggressin) from the peritoneal cavity of guinea-pigs. The rabbits proved poor animals for the work, as they developed hypersensibility to the injections, from which many died. They had the further disadvantage of yielding small quantities of serum. The goat proved a satisfactory animal to immunize, since it bore the injections well and developed an agglutinating serum in a relatively short time. The early experiments showed that rabbit serum was very poisonous for guinea-pigs when injected into the peritoneum in doses above 0.5 c.c. The first tests of the protective powers of the goat's serum were made with the serum obtained at the bleeding on Nov. 18, 1905. The guinea-pigs were of 250 gm. weight. Serum injections were made (1) twenty-four hours before the cocci were injected, and (2) simultaneously with the injection of the cocci. The pigs receiving the serum survived; the control pigs died. The quantity of goat's serum used was 1 c.c., and the injections were made intraperitoneally or subcutaneously; the cocci were injected into the peritoneal cavity. The next test of the serum was made three days later. The serum was given again subcutaneously and intraperitoneally, and, besides the ordinary controls, a set in which bouillon was injected was also employed. The cocci were injected thirty hours after the serum and bouillon. The control pigs, including those given bouillon, died during the night. The pig given 0.1 c.c. of the serum into the tissues of the back died in about the same time. The pigs which received 0.1 c.c. of serum intraperitoneally and 1 c.c. subcutaneously survived. The next experiment to be reported was made Feb. 26, 1906, with the serum of a rabbit injected with the diplococci and guinea-pigs' aggressin. The control pigs died in from fourteen to seventeen hours. The antiserum was given simultaneously with the cocci, and the pigs receiving 0.1 c.c. intraperitoneally and 0.5 c.c. subcutaneously survived, while those given 0.5 c.c. intraperitoneally and 0.1 c.c. subcutaneously survived longer than the controls, but finally died. Thus it is seen that by preceding the injection of cocci with a prophylactic dose of serum, or by injecting serum and cocci simultaneously, the lives of the guinea-pigs can be saved. Dosage of rabbit serum is important. Too little serum fails to protect, and too much serum, at least in case of rabbit serum, prejudices the result by reason of its own toxicity. Therapeutic tests were made with antiserum from the rabbit, with the result that some pigs were saved with a dose of 0.5 c.c. one hour after infection. When this dose was exceeded the serum poisoning accelerated the fatal action of the cocci. After several months' additional injection of the goat its serum was again tested. The bleeding of March 14, 1906, was used in the subsequent experiments. This goat's serum was found to be certainly protective by simultaneous injection in doses of 0.1 c.c. and variably protective in doses of 0.02 to 0.01 c.c. It was also effective as a therapeutic application when given intraperitoneally in a dose of 0.1 c.c. two hours and four hours, respectively, after injection. Infected pigs could not be saved by means of subcutaneous injections of even larger quantities of serum after the lapse of several hours. The difference which the time interval makes is shown by the loss of weight (25 per cent.) suffered by the pig treated four hours after infection.

---

[2] It is now known that the diplococcus appears in the circulating blood in epidemic meningitis. It is noteworthy that the diplococcus invades the blood from the spinal canal in inoculated monkeys.

The first test of the goat's serum on the monkey was made on Dec. 2, 1905. Two spider monkeys (South American) were inoculated at 12 o'clock noon with cultures of the diplococcus. At 3 p. m. the same day one was given 2 c.c. of the serum into the spinal canal. Both animals became very sick; the control monkey finally recovered and the treated monkey succumbed during the night. The serum-treated animal became rapidly worse after the serum injection, showing the ill effect of the injection. The lesions found at autopsy were very severe and of a character which was taken to indicate that goat serum can not be injected with impunity into the inflamed spinal canal of the monkey.

Two large monkeys (*Macacus nemestrinus*) were immunized, as stated, for the production of an homologous serum to be tested chiefly on monkeys by intraspinal injection. Injections of diplococci and of exudate (aggressin) from guinea-pigs were made during a period of nine months. The animals were bled June 15, 1906, and the serum tested. A series of five monkeys (*Macacus rhesus*) was treated with the serum, a control animal having been inoculated in each case. These experiments will be given in brief form. The control monkeys for each experiment succumbed. Before giving the protocols of these experiments it should be stated that, with one exception, the same strain of coccus was employed. It was found that of the standard suspension 0.5 c.c. caused death in about fifty hours and 1.0 c.c. in twenty-two hours. For the serum tests the larger dose was used.

Experiment, July 3, 1906: Medium-sized *Macacus rhesus* given at 11 a. m. 1 c.c. emulsion of diplococcus No. 596, together with 1 c.c. of monkey antiserum No. 1. Fluid flowed from the needle before injection. July 4, 9 a. m., monkey appears normal, active, on perch. Lumbar puncture yields several drops of faintly turbid fluid, which shows on cover slips free diplococci and leucocytes in moderate numbers, some of which contain diplococci, staining poorly. Cultures from the fluid negative. July 5, 11 a. m., monkey apparently well. Lumbar puncture gave a small amount of clear fluid, which contained neither leucocytes nor cocci. Cultures negative. July 10, the monkey remains well.

Experiment, July 5, 1906: Medium-sized *Macacus rhesus* given 1 c.c. suspension of culture No. 596 at 11:45 p. m. Fluid flowed from needle before injection. At 2 p. m. the monkey was sick. Lumbar puncture gave a small quantity of rather thick, opaque fluid. One cubic centimeter of immune serum injected rapidly. Immediately at conclusion of injection pressure symptoms of an alarming character developed. The animal was prostrated for two hours, after which it slowly got better. At 6 p. m. it responded to disturbance. At 8 a. m. next day the monkey was up and appeared well. It remained so subsequently. The cover slips from the exudate of the lumbar puncture showed many polymorphonuclear leucocytes and a small number of lymphocytes, many extracellular and a few intracellular diplococci.

Experiment, July 13, 1906: Moderately large *Macacus rhesus* given at 11:15 a. m. 1 c.c. emulsion of coccus No. 596. Although no fluid was obtained, the canal was certainly entered; 4 p. m., animal sick; 5 p. m., depressed, but still sits up. Lumbar puncture gave a small quantity of turbid fluid, but during the operation the animal collapsed; 1 c.c. of serum injected slowly. The monkey was watched until 10 p. m.; no progress of the disease. July 14, 10 a. m., animal appeared well. No future symptoms developed. The fluid obtained by lumbar puncture showed many leucocytes with an occasional intracellular coccus, and extracellular cocci.

Experiment, July 27. 1906: At 8:45 a. m. a medium-sized *Macacus rhesus* was given one full agar slant culture No. 610, eighteen hours old, suspended in salt solution, into spinal canal. Fluid obtained before injection. At 11 a. m. 5 c.c. of antiserum from monkey No. 2 was injected into the skin of the thigh. Before the serum injection the animal was sick; it lay half down on the bottom of the cage. No immediate effect followed from the injection, but the symptoms did not progress. The next day the animal appeared well. Lumbar puncture was unsuccessful after the injection until the next day, at which time clear fluid, containing neither cocci nor leucocytes, was obtained. The control for this monkey was a much smaller and weaker monkey of the same species, which succumbed in eight hours.

I do not regard this experiment as entirely free from doubt, but as I was unable to obtain more monkeys at this time the experiment could not be repeated.

This series of experiments was, up to this point, successful. But I must record a failure under conditions which, in view of the foregoing successful tests, was wholly unexpected:

Experiment, July 20, 1906: Medium-sized *Macacus rhesus* given at 12 m. 1 c.c. of emulsion of coccus No. 596; 3 p. m., 1 c.c. of antiserum injected intraspinally. This monkey was sick when given the serum and the symptoms progressed fairly rapidly. At 11 p. m. the animal was much prostrated and sat in the cage with head depressed. It died about 7 a. m., July 21. The autopsy showed a very unusual amount of exudation in the membranes of the cord. Cover-slip preparations showed a purulent exudate with large numbers of cocci, all of which were within polymorphonuclear leucocytes. The exudate in the meninges of the brain and cord showed the same condition of complete phagocytosis, although the number of leucocytes and cocci was smaller. The fluid withdrawn by lumbar puncture before the serum injection contained large numbers of diplococci and very few leucocytes; an occasional leucocyte contained diplococci. Cultures from the meninges of the cord, medulla and cortex and from the lateral ventricle were positive; those from the heart and bone marrow of the femur were negative.

In describing the characteristic lesions in the guinea-pigs the occurrence of hemorrhages in the mesentery, diaphragm and adrenals were noted. It was found that the antiserum prevented the appearance of these lesions, even when they failed to save the inoculated pigs. The immune serum from the monkey was effective in the guinea-pig, although this serum possesses apparently greater native toxicity for guinea-pigs than goat serum.

The experiments here briefly described have, possibly, some value in aiding us to understand better the manner in which *Diplococcus intracellularis* brings about its peculiar effects in human beings. They would also seem to show that the diplococcus is an organism possessing highly interesting and very peculiar biologic properties. The special experiments dealing with the prophylactic and therapeutic properties of antisera prepared from the diplococcus are sufficiently encouraging to be more widely and closely studied. In how far the results obtained on guinea-pigs and monkeys can be applied to the prevention and treatment of cerebrospinal meningitis in man it is not safe to predict. Should further experiments show that subcutaneous or intravenous injection of antisera can modify favorably the experimental disease in monkeys, the case would be not without hope. I do not think that the injection into the spinal canal of man of alien sera should be undertaken until their physiologic action has been worked out in more detail in monkeys. Were it practicable to employ monkeys for producing the antisera to be used in man, the danger of serum intoxication might be lessened, while the good effects of the immunity principles were retained. It is my intention to continue the studies already begun along these lines.

TUMORS OF THE CAROTID GLAND.

W. W. KEEN, M.D., LL.D.
Professor of Surgery, Jefferson Medical College.
and
JOHN FUNKE, M.D.
Demonstrator of Morbid Anatomy, Jefferson Medical College.
PHILADELPHIA.

(Concluded from page 479.)

PATHOLOGIC PART BY DR. FUNKE.

A knowledge of the normal gland would facilitate the study of the tumors arising from the carotid gland, but the lack of this information has led to the existing confusion with regard to the classification of the neoplasms. Then, too, the obscure embryology adds to the confusion.

EMBRYOLOGY.

In 1881 Stieda[23] attempted to enlighten us on this question. He found a triangular cell collection connected by means of a fine fibrous strand with the mouth epithelium on the one hand and with the thymus gland on the other. In embryos of 36 mm. the cell collection was round and no longer connected with the structures just named. The cell collection, he holds, gives rise to the carotid gland. In sheep embryos of 10 and 11 mm. the gland is first seen as a thickening of the posterior portion of the horizontal branch of the branchial cleft, from the superior part of which the thymus develops. Like Stieda, Rabl (cited by Paltauf[2]) holds this organ to be epithelial in origin. He found in mammifera and in birds that the endoderm of the third branchial cleft furnished the ventral diverticulum for the thymus and a dorsal bud for the intercarotid gland. Pierre de Meuron,[24] holding that the carotid gland develops from the third branchial cleft, found it in sheep near the bifurcation of the carotid artery, but in embryos of 18 mm. it was not separated from the thymus. Born[25] is inclined to believe that the structure described as the carotid gland by these authors separates from the parent body and develops into the accessory thyroids. Contrary to the views of the authors who hold the organ is of epithelial origin, Fischelis[26] maintains that the carotid gland develops from the tissues lying between the approximating ectodermal and endodermal layers, but it does not develop from epithelial structures. Katschenko,[27] who, perhaps, has done, if not the most recent, the most thorough work in this direction, takes the ground that the carotid gland arises from a slightly thickened portion of the adventitia of the internal carotid artery near the bifurcation of the common carotid, and that the first evidence of the structure is seen in embryos of 14 and 15 mm. as an ellipsoidal body composed of loosely woven, richly cellular connective tissue. In embryos of 30 mm. he found the portion of the gland nearest to the bifurcation thickened, while that part farthest from this point was thinner; in still older embryos the gland was found nearer the bifurcation. The structure described by Stieda, Rabl and Pierre de Meuron, according to Katschenko, was the upper part of the thymus anlage—the *nodulus thymicus*. Paltauf's[2] investigations lead him to conclusions similar to those of Katschenko; in embryos of 4.5 cm. (Fig. 22*) Paltauf found the organ at the posterior part of the common carotid at the bifurcation. The pictures Paltauf found during his investigations of the carotid gland of rabbits, cats, calves and human beings were so nearly uniform that, according to his views, the anlage is connective tissue rather than epithelial. In snakes Van Bemmelen (cited by Priceteau[28]) found that the organ develops from the endoderm of the third branchial cleft. Prennant (cited by Priceteau) comes to similar conclusions, while Priceteau[28] himself maintains that the carotid gland develops from the third branchial arch and arises from the structure, which gives origin to the common carotid artery. Borst[29] tells us that the organ is derived from the mesenchyme, while v. Heinleth holds that it arises from a cellular thickening of the posterior and outer periphery of the primitive carotid. Differing, but not widely, from some of the opinions given, are the views of Kohn,[30] whose investigations led him to view the origin of the organ as distinctly nervous, maintaining that it developed from the embryonal ganglion cells of the intercarotidal plexus, a view long entertained by Luschka.[31] In embryos of 4 months Marchand found the gland surrounded by loosely woven connective tissue, in which were many blood vessels and nerves.

* The twenty-four illustrations, including three views in colors, appeared in the first portion of the article published last week, August 18.

While many views have been expressed with regard to the development of this organ, the trend of opinion of the recent writers looks more favorably on the researches of Katschenko and Paltauf, and tumors arising from the gland are being classified according to the views of these authors, although the grouping would be more satisfactory if the embryology were definitely known.

HISTOLOGY.

The controversial views of the architecture of the normal carotid gland entertained by Luschka[31] and J. Arnold[32] are interesting from an historical point of view and illustrate how both the contending parties may be right in a certain measure. In my first paper[3] I took the ground that the gland was not constantly present; in my recent investigations I have been more successful in finding the organ. The size of the gland varies slightly, according to different authors. Mönckeberg[11] gives its length as varying from 5 to 7 mm., its breadth from 2.5 to 4 mm., its thickness 1.5 cm. Reclus and Chevassu[15] say that it is 7 mm. long. At times it is found on the posterior aspect of the common carotid just below the bifurcation, but most frequently on the inner and posterior side of the internal carotid at the origin of the vessel, where it is attached to the artery by means of a thin strand of fibrous tissue containing its blood vessel, which in embryos of 4 cm. Paltauf found arising from the external carotid. In my recent work I found it lying on the external carotid in the bifurcation.

According to Marchand[1] and Schaper[33] there exists a hilus-like structure where the artery enters the gland. The organ has a distinct capsule, which, according to nearly all authors, contains both types of nerve fibers. The capsule sends forth prolongations that enter the underlying structure and divide the organ into lobules, which are again divided by delicate strands of fibrous tissue or capillaries, or both, inclosing the so-called *Zellballen* (Figs. 23 and 24) of the German writers; each lobule receives a branch from the main artery, so that the number of lobules constituting the gland corresponds to the number of branches the main artery possesses. In the lobules the branches form capillaries, producing a structure which, according to Schaper, conforms to the architecture of the gland described by J. Arnold. This writer, who maintained that the essential part of the organ consisted of the glomeruli which are formed of a capillary network, is supported in his contention by Pfoertner,[34] Eberth[35] and Frey.[36] Paltauf, on the other hand, does not hold the organ as a typical glomeruluslike structure, but maintains that in addition to the glomeruli there are large cells lying in close association with the blood vessels and at times lining spaces.

It is very interesting to note that in this controversy between Luschka and Arnold with regard to the structure of the organ, each side had some grounds on which to base its argument, and it is also interesting to note that while most authors now regard the carotid gland as largely a vascular structure and that the cells of the organ are in some way intimately related to the capillaries, recent experiments indicate the correctness of the view expressed by Luschka that the carotid gland is analogous to the coccygeal, the suprarenal glands and to the hypophysis cerebri. Because of the organ's close proximity to the cervical ganglia and because of the presence of many nerve fibers in the gland Luschka regarded it as a nervous structure. Paltauf suggests that later we may recognize a close relationship between the nervous system and the gland.

It must be admitted that the arrangement of the cells of the carotid struck Luschka as being like that of an epithelial gland and that he did not recognize the irregularly arranged and irregularly distributed chromaffine cells, the elements on which the secretory properties of the organ depend. The vessels of the carotid gland, that is, the branches of the main artery, are of considerable size; occasionally they are small and contain but few red blood cells or granular detritus.

Marchand states that the structure of the gland is difficult to determine, but that it is composed of two essential elements, namely, blood vessels and cells. The cells are large, polyhedral, round or oval; the protoplasm is granular and stains faintly. Mönckeberg speaks of protoplasmic prolongations which are occasionally found. The nuclei of the cells are circular or oval and, like the protoplasm, react poorly to the stains. Although the arrangement simulates gland structure, the phenomenon is too inconstant to ascribe to the cells a definite arrangement, but in nearly all instances they are intimately related to the blood vessels; in fact, so intimate is this relation that Marchand is strongly inclined, even in the adult gland, to regard the cells as derivatives of the capillaries. Marchand, and recently Mönckeberg, have pointed out that the capillaries sometimes appear to penetrate the cells, a phenomenon frequently observed in my studies of the normal gland. Paltauf holds that the fibrous reticulum is in no way related to the cells, except to act as a sustaining frame. He notes that the reticulum is not developed to the same extent at all points; occasionally it is so inconspicuous and the nuclei of the cells are so prominent that it is difficult to determine whether these nuclei belong to cells poor in protoplasm or whether they belong to giant cells. Schaper, on the other hand, did not find the reticulum described by Paltauf, whose findings Schaper regards as postmortem changes. According to the last-named author the trabeculæ arising from the capsule divide the organ into secondary nodules, the fibrous tissue around which penetrate them and surround the *Zellballen,* the elements of which, Schaper holds, are not identical with the cells lining the blood vessels, thus controverting Marchand's view. Schaper bases his opinion on the fact that the endothelial cells of the capillaries are never absent. The typical relation of the cells to the capillaries occurs at those points where the cells in a single layer form partially closed spaces, the relatively small lumina of which may contain one, two or even three capillaries.

Among the cells of the lobules and in the stroma are a different type of cellular elements, to which Stilling[37] applied the term "chromophile" and which have recently been described by Kohn, who termed them "chromaffine" cells because of their affinity for the chrome salts. The recent work of Mulon[38] attributes to these cells an important functional significance. Similar or, perhaps, identical cells have been found in the suprarenal glands

as early as 1865 by Henle.[39] These cells have been found in the coccygeal gland, the hypophysis cerebri and in the abdominal sympathetic ganglia. Mulon made extracts from the carotid glands of horses and injected this substance into the veins of rabbits, where it invariably produced a rise in the arterial pressure and sometimes produced an acceleration of the beat and force of the heart. Mulon concludes that the chromaffine cells secrete a substance which, when introduced into animals, acts like adrenalin in raising the arterial pressure. The structures containing these cells he terms "chromaffine organs," and holds that they present some connection with the sympathetic system. If these experiments are corroborated the organ will necessarily have to be termed a gland instead of a body.

TUMORS OF THE CAROTID GLAND.

The tumors, Marchand maintains, arise as a result of the proliferation of the cells of the gland. The growths are either lobular or lobulated; sometimes they are the shape of a small kidney. Lobulation is not infrequent, because of the location of the neoplasms, which during their development grow on either side of both the internal and the external carotid arteries; then, too, the broad septa which penetrate the tumors draw in the capsule at various points and thus produce the lobulated condition. If the tumors remain globular they may push upward as they develop, increasing the angle of the carotids and finally lie on the vessels. This fact was noted by Reclus and Chevassu. Gilford and Davis noted that, while their tumors were adherent to the carotid vessels, they rested on these structures. Marchand says they rest on the carotid arteries as the thyroid rests on the trachea, but the tumors in addition encircle the vessels.

The consistency of all the reported growths is not uniform. Paltauf's first case presented a firm tumor and his second was less firm, but not soft. Kopfstein speaks of a firm growth; the three reported by Gilford and Davis were hard, and the first tumor which Mönckeberg reports was firm; Scudder's and Kretschmann's tumors possessed a similar consistency. The greater number of the reported cases were soft; indeed, some authors speak of a brain-like consistency. Case 22 of the reported series was elastic and soft, and Cases 26 and 27 were softer. The consistency depends largely on the amount of fibrous tissue present and also on the degree of the blood-vessel distension.

The color varies from a reddish-gray to a gray or a brown. Few authors report the gray color seen by Gilford and Davis. Kopfstein and von Heinleth state that the color of the tumor simulates the tinge of a parenchymatous goiter. Reclus maintains that the color ranges from a brownish-violet to a pure violet.

Encapsulation is present in all cases, and although the capsule is most frequently adherent to the surrounding structure it is occasionally free. If the carotid arteries are not embedded in the tumor there are, as a rule, two grooves, either on the anterior or on the lateral surface of the growths. This is due to the fact that as the neoplasms develop there is a tendency to grow posterior to the carotid vessels. The capsule gives rise to many bands that can be identified macroscopically and which penetrate the underlying structure, where they gradually become lost. Occasionally the cut surfaces of the tumors contain large masses of fibrous tissue at some points, usually near the center of the growths.

The blood vessels are a conspicuous feature of the tumors. They are found in the capsule and in all parts of the growths. So abundant are these structures that the cut surfaces of the neoplasms appear sponge-like.

While these tumors often differ in their minute structure, the histology, in a general way, is identical in nearly all the reported cases. The capsule is always described as containing arteries and veins in considerable numbers. Nerve fibers of both the medullated and the nonmedullated types are found by all writers, but I must confess that I have not succeeded in demonstrating these structures in any of the tumors I have had occasion to examine. The fibrous septa mentioned in the gross description as arising from the capsule are more abundant in some tumors than in others; Case 22 was particularly rich in this respect. These penetrating bands, which contain small and large blood vessels, take part in the production of the alveolar architecture, which is a characteristic feature of these growths. Paltauf and Kopfstein speak of the hyalin degeneration these septa suffer. This change was more marked in Case 22 than in Cases 26 and 27. Von Heinleth holds that this change is incident to alterations in the capillaries; the cells lining these structures by overproduction cause occlusion of the lumina of the vessels and thus give rise to hyalin degeneration of the neighboring tissue, as well as the capillaries themselves.

The blood vessels alone, in a large number of cases, form the walls of the alveoli, but occasionally the capillaries are supported by thin fibrous strands, constituents of the fibrous septa. In Case 22 the walls of the alveoli were uniform in thickness and rarely did the capillaries alone form the alveolar walls; in Cases 26 and 27 they were less uniform in thickness and not infrequently, in fact most frequently, they were formed by the capillaries alone or by a single layer of endothelium. Many of the walls were difficult to determine. It is not a rare occurrence to find large vessels from which smaller ones arise and anastomose with other capillaries, forming in that way the walls of the alveoli. The capillaries vary with regard to their structure; occasionally the walls are composed of a single layer, occasionally there appear to be two layers of endothelial cells; in others the endothelial lining is supported by thin fibrous strands.

The size of the alveoli varies. In Case 22 they were fairly uniform, ranging from 0.05 to 0.1 mm. in diameter, while in Case 27, or the tumor reported in this paper, they varied considerably; some possessed a diameter of 0.4 mm. The shape, like the size, varies; in Cases 22 and 26 they were all either circular or oval; in Case 27 the one diameter exceeded the other four and five times, the contained cells forming long strings, like those constantly seen in endotheliomata.

The spaces or alveoli invariably contain tumor cells, which are, as a rule, large and polyhedral in shape, although this varies according to the amount of pressure exerted, and, since the cells possess no limiting membrane, but little force is necessary to influence the shape. Oberndorfer tells us that in his tumor the cells were small but the protoplasm comparatively large. Mönckeberg speaks of the relatively long protoplasmic prolongations as being present among the polyhedral, spindle- and triangular-shaped cells of the alveoli. Paltauf refers to the protoplasmic processes, which, he says, are found among the cells at the peripheries of the *Zellballen* and which protrude into the walls of the capillaries; this phenomenon suggests very strongly to Paltauf that the cells of the spaces are derivatives of the capillaries forming the walls of these structures. Because of the absence of the limiting membrane, the granules of the protoplasm are not closely set and consequently, in a large majority of instances, this substance is transparent. In Case 27 I found vacuolation a few times. In Cases 22 and 26 the cells showed no such condition. Mönckeberg found glycogen in the tumor cells examined in the fresh state, and maintains that the vacuolation found in these structures by other authors is due to glycogenic infiltration. The demonstration of this substance further illustrates the resemblance of the carotid gland to the suprarenal glands. Perhaps further studies instituted by Mulon will bring to light still other similar features in these two organs, so widely separated topographically.

---

[39] Henle: Zeitft. f. rationalle Med., 1865.

Oberndorfer speaks of a foam-like appearance of the protoplasm of these cells, which he believes to be due to the presence of fat globules or glycogen, but because his specimens were not examined in the fresh state it could not be determined which of the two substances was present. The number of cells in each alveolus varies in different tumors and also in the same growth. In Cases 26 and 27 the spaces were so well filled that it was extremely difficult to identify the boundaries of the alveoli in many parts of the tumor. Marchand in his paper called attention to this feature.

The nuclei of the cells are, as a rule, large; of course, they vary and sometimes they are small in comparison to the size of the protoplasm; some are circular, others are spindle-shaped, but the greatest number are oval: all are vesicular. The nuclei can be studied to a greater advantage owing to the fact that they are so readily outlined. The nuclear membrane is always conspicuous; the amount of chromatin varies in the same growth and in different growths. The chromatin in the nuclei of the tumor cells in Cases 22 and 27 was very much less than in Case 26, in which the staining of these structures was intense compared with the other cases named. In Cases 22 and 27 the centers of the nuclei were very often occupied by a hyalin substance, now and then traversed by a delicate chromatin-containing strand. It is not an uncommon thing to find among the *Zellballen* red-blood cells; in fact, nearly all writers on the subject speak of their presence. Mönckeberg found alveoli where the tumor cells had been almost entirely replaced by the blood. In addition to the blood cells Paltauf found fibrin. Red blood cells were present in greater abundance in Case 27 than in Cases 10, 22 and 26. Marchand notes that in his tumor the cells were placed so loosely in the alveoli that the dislodgement was readily accomplished. Leithoff calls attention to the fact that in the tumor of which he writes the alveoli contained many cells, the protoplasm of which was scanty, but the nuclei were prominent and rich in chromatin. He states that they bear a striking resemblance to sarcoma cells.

Occasionally the tumor elements, instead of being inclosed by the delicate fibrous tissue strands or the capillaries, are disposed around cross-sectioned vessels, there being no definitely formed alveoli. Here occasionally one finds tumor cells placed at right angles to the blood vessels. Leithoff[40] maintains that such an arrangement is a frequent occurrence, while Mönckeberg holds these pictures as coincidents rather than as specific arrangements. Now and then one finds tumor cells, as pointed out by Oberndorfer, arranged around small spaces forming structures like acini. Paltauf referred to these pictures as spaces in the *Zellballen*. Marchand observed certain cells which he maintains resembles syncytium and regards them as probably the result of confluence of several tumor cells. Oberndorfer speaks of similar structures. Mönckeberg and also Gilford and Davis found elements containing nuclei; they look on them as giant cells; similar structures were found in Case 26.

The source of the tumor cells is still an unsettled question. Von Heinleth declares that the tumor elements not only lie on the capillaries, but are derivatives of those structures. Marchand is of the same opinion. There are points in the sections that appear to me to indicate that the cells must be derivatives either from the endothelium or, what is more probable, from the cells around the capillaries, which are perhaps identical with the endothelium. There is, of course, no method by which we can determine definitely that the tumor elements are derivatives from either the lining of the capillaries or the cells around these vessels. In Cases 26 and 27 it was no uncommon thing to find capillaries with a single layer of endothelium forming the alveolar walls, to which were partially attached cells jutting into the alveoli and among the contained cells.

Kaufmann and Ruppanner exclude the carotid tumors reported by Gilford and Davis, but Dr. Keen has included them in the series. The ground on which Kaufmann and Ruppanner make the exclusion seems to me insufficient; the only sound point in their argument which can possibly carry weight is the fact that the tumors were found lying on the carotid arteries instead of behind and between them; in the gross description mention was made of the fact that if the tumors remain globular they may push upward, increasing the angle of the carotids, and finally may lie on these structures. In the second case of the Gilford and Davis report the statement is made that the tumor was also between the vessels. While it is the rule to find the tumor extremely vascular, yet in the same case they say that in some areas the tumor was soft and red in color; the prevailing tinge was gray. It must be admitted that the microscopic description is very superficial, yet they speak of the alveolar arrangement of the cells and of the fine capillaries in the walls of these structures; their description of the tumor elements corresponds to the cells found in carotid tumors; they also found red cells among the tumor elements in the alveoli, a constant feature of these neoplasms. Giant cells which they found have been mentioned by several authors.

By some these tumors have been termed angiosarcomata, but most writers have called them peritheliomata. Leithoff,[40] because of the abundance of the small cells in the alveoli, declared the tumor of which he wrote was a perithelial sarcoma. Paltauf maintains that histologically the perithelial cells do not differ from the endothelial, consequently there is no sound basis on which the term perithelioma is placed, yet he maintains that multiplicity of names, when associated with the proper conception, does not constitute a source of confusion. I am inclined to simplicity and would suggest that the tumors be called endothelioma, notwithstanding the fact that I applied the term perithelioma to the tumor in Case 22.

DISCUSSION.

Dr. Joseph D. Bryant, New York, said that he had never met with a case of this kind and had been able to learn of but one, and this only after consulting with the pathologists of his city. It occurred to Dr. Bryant that the interference of the circulation referable to the brain would be an important matter to consider and, therefore, he consulted the classic essay of Dr. Wyeth, published some years ago, bearing on the surgery of the carotid artery, and found that he had collected 789 cases of ligature of the common carotid, 95 or 12 per cent. of which caused more or less disturbance of the cerebral circulation. From this 95, he selected 62 cases and arranged them according to age and sex.

---

[40] Leithoff: Dissert., Wurzburg, 1904.

Of these 62 cases under 25 years of age there were 21 cases in which cerebral disturbances ensued, following ligature of the common carotid; 7 females and 14 males. Of the 7 females, four recovered and three died. Of the 14 males, three recovered and eleven died. Twenty-eight cases were noted between 25 and 50 years of age, 6 females and 22 males. Of the 6 females, one recovered and five died; of the 22 males, 6 recovered and 16 died. From fifty years and upward there were thirteen cases, eight males and five females. Of the eight males, two recovered and six died. Of the females, all died. These cases are interesting, because they illustrate very forcibly the effect of ligature of the common carotid arteries, but this list can be regarded only as suggestive, since many of the cases were of greater significance in other respects than ligature of the vessels for carotid tumors. The latest general statement regarding deaths in ligature of the common carotid shows that of 834 patients, 327 died; of the total number (834), 789 were ligatured before asepsis, 323 of whom died. Of the remaining 45 ligatured under asepsis, but 4 died, showing at once the great importance of modern methods.

PARAFFIN PLATES AS AN AID IN OPERATIONS FOR EXTENSIVE SYMBLEPHARON

AND FOR THE RESTORATION OF CUL-DE-SACS FOR PROTHESIS.*

WILLIAM H. WILDER, M.D.
CHICAGO.

Symblepharon of severe degree, because of extensive destruction of the conjunctiva, has long been a *bête noir* for the ophthalmic surgeon. I do not intend to consider in this paper those simpler cases in which there is a limited destruction of the conjunctiva and slight band-like adhesions between the eyelid and the ball, for these can easily be relieved by the exercise of some ingenuity on the part of the surgeon and the transplantation of flaps of conjunctiva by one of the many methods that have been devised by different operators. I propose, however, to consider those severe cases in which, from injury, burn or ulceration, there has been extensive destruction of the conjunctiva, and a great part or the whole of one or both lids has become firmly adherent to the eyeball.

My subject also includes those more difficult cases of atrophy of the conjunctiva, sometimes almost total, resulting from ulceration, burn, cicatricial growth in the orbit from cellulitis after an imperfect operation of enucleation, in which an artificial eye can not be worn and which are brought to the surgeon for prothesis. Such cases of total symblepharon have been a dread to every ophthalmic surgeon, and, as stated by Arlt years ago, are for him a *noli me tangere.*

Knapp[1] stated:

> In spite of the numerous attempts which, during the last twenty-five years, have been made to remedy this unfortunate condition by grafting skin or mucous membrane of all possible localities and in all possible manners on the atrophic surfaces, I have not seen, either in New York or in my travels, a single case that had been more than a temporary improvement, including even the cases in which the object aimed at was only to fit a stump for the prothesis of an artificial eye. All these grafts, if they take root at all, sooner or later ulcerate and slough or shrink to nothing.
>
> The older methods of securing free space by putting between the wounded surfaces foreign bodies, e. g., plates of metal, have been abandoned.
>
> The grafting of small pieces of skin or mucous membrane on wounded surfaces had practically to be given up when tried on the conjunctiva. The unavoidable movements of the eye almost always prevented them from taking root.

I make this rather extensive quotation from such an eminent authority as Dr. Knapp to show that as late as 1898 the application of grafts for the purpose of making an artificial fornix was unsuccessful, and the same was said of transplantation of skin flaps from the lid or cheek.

The reasons for failure are apparent. Thick-skin grafts, such as Wolff grafts, are more likely to slough than the thinner Thiersch grafts. Again, the latter are not likely to grow unless they are perfectly and evenly applied to the wound surface, and this is accomplished with difficulty in the case of a cul-de-sac or fornix that has to be lined unless we use some means that insures perfect and even coaptation. This is not accomplished by the use of sutures placed through the graft and fornix, for these tend to wrinkle it, but such sutures may have a distinct advantage if used according to the method practiced by Weeks,[2] so that they will pass through the firm tissue of the periosteum in their course to the cheek and so anchor the graft firmly and reduce to a minimum contraction of the new fornix.

The ideal operation for symblepharon will be that which will bring about permanent restoration of the fornix and secure mobility of the eyeball, or, if the eyeball is absent, furnish a cul-de-sac deep enough to allow an artificial eye sufficiently large to be worn. This ideal operation must remove any cicatricial tissue that causes thickening and deformity of the lid, or that would by its contraction cause shrinking of the newly made cul-de-sac.

The new cul-de-sac must be lined with epithelium, and for this purpose one would preferably select conjunctiva if that were available, but this is not easy to obtain, although for operations of limited extent the conjunctiva of a rabbit or a dog may be used.

In this particular we can not attain our ideal and are forced to take epithelial structure from some other part. Mucous membrane from the lip may be used, but here again the amount is limited and it is difficult properly to sterilize it and to remove it in thin layers, such as are required. Furthermore, such grafts are more liable to shrink than those taken from skin surfaces.

The lining graft should be thin and membrane-like, and so if mucous membrane is not available Thiersch grafts of suitable size may be used instead. These, as originally pointed out by Hotz,[3] answer almost every requirement, although, naturally, there are some objections to their use. The membrane must be perfectly fitted to line the pocket and must not wrinkle or fold, but must be perfectly coapted; otherwise it will not attach itself and will slough away. The introduction of some mechanical appliance, such as a plate, that will press the graft evenly and firmly into every part of the new cul-de-sac, and will at the same time immobilize the part, so that healing will take place promptly, a plate that can be easily removed if desired and as easily replaced, that will not irritate by its presence; such a method would approach the ideal.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

[2] Weeks: Trans. Sect. on Ophth., A. M. A., 1902. Trans. Tenth Cong. Ophth., Lucerne, 1904.

[3] Hotz: "The Use of Thiersch Skin Grafts as a Substitute for Conjunctiva." Ann. Ophth., April, 1893.

A number of years ago, before the introduction of plates for this purpose, I tried in several cases to hold the graft smoothly in place by pouring melted paraffin into the freshly lined pocket, but the paraffin had to be of such low melting point to avoid injury to the tissues that it was not firm enough to give the needed support. In some simpler cases it seemed to suffice, but it would not meet the requirements in the more difficult ones. I made mention of my experience with this method a number of years ago in a discussion on this subject in this section, but I have since abandoned its use.

Nothing answers so well the purpose of holding the graft in position as some form of plate. In 1898 Morton[4] recommended the use of a prothesis to hold the grafts in place, and a little later May[5] contributed reports of several cases successfully treated by this method. He uses a shell of porcelain or glass, shaped like an artificial eye, on which the Thiersch graft, with its raw surface outward, is placed. This shell is then placed in the newly made cul-de-sac, so that the raw surfaces are brought into contact. Fine sutures unite the edge of the graft with the edge of the wound.

A number of operators have reported satisfactory results in operating for total symblepharon by implanting Thiersch grafts and holding them in place by a glass or porcelain prothesis after the method of Morton and May. Among these are Natanson,[6] Grunert,[7] Gullstrand[8] and Abadie.[9]

Weeks recommends a plate made of "base gutta percha" about 1 mm. thick, such as is used by dentists, which is molded into proper form after dipping it into hot water. The Wolff graft that he uses is secured by loop sutures that pass through the firm periosteum at the orbital margin, and is then held in place by the gutta-percha plate.

Hotz[10] employs a lead plate (Fig. 1) that is shaped to fit the new cul-de-sac. The Thiersch graft is first spread out over the wounded surface and the edges united with fine sutures. After this is accomplished the lead plate is placed in position and stitched to the lid through holes previously drilled through the plate. This holds the graft down into the deepest part of the cul-de-sac.

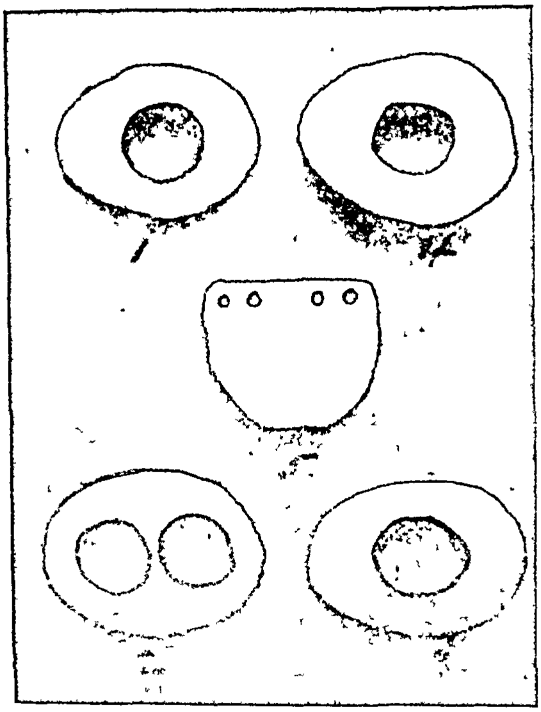
H. W. Woodruff[11] employs much the same method, preferring, however, to make the plate of block tin. He spreads the graft over the edge of the plate, raw side outward, and then inserts it carefully into the new cul-de-sac. He does not attempt to suture the edge of the graft to the conjunctiva (a manifest advantage if it can be dispensed with), but in sewing the plate to the lid he passes the thread through that part of the graft that lies next to the lid. Only one lid is operated on at a time.

I have seen the results of some of Dr. Woodruff's operations and can testify to the value of the method. Indeed, his success prompted me to endeavor to add something to the technic of this difficult work.

The method of operation that I now employ, a modification of the plate or prothesis method, has proved so successful in my hands in a number of difficult cases that I venture to recommend it. Metal plates, preferably of soft sheet lead or block tin that can be easily cut to any size or molded to any shape, are coated with hard paraffin of high enough melting point so that the temperature of the body will not melt it and so expose the metal plate. Such a paraffin plate is perfectly smooth and can do no harm to the cornea.

Through the center of the plate a hole about the size of the cornea has been made, and through this the cornea can be seen and treated if necessary while the plate is in position (Fig. 1).

In operation on cases of obliteration of the conjunctival sac, the eyeball being absent, I use a paraffin plate of a size large enough to fill out both cul-de-sacs, and in the center of this plate have two or three holes, through which the orbit can be easily irrigated while the plate is in position. Furthermore, the band of metal separating these openings furnishes a good handle for the forceps to seize while inserting or removing the plates.



Figs. 1 and 3.—Lead plates prepared for symblepharon operation, the cornea being present.
Fig. 2.—Lead plate used for restoring cul-de sacs for prothesis. This would be coated with paraffin.
Fig. 4.—Similar plate coated with paraffin.
Fig. 5.—Lead plate to be sewed to the lid in the method of Hotz and Woodruff.

TECHNIC.

The technic of an operation for symblepharon of one or both lids when the eyeball is present and the cornea is intact or partially so would be as follows: In many cases local anesthesia will suffice. In addition to 4 per cent. cocain solution externally, hypodermic or subconjunctival injections of 0.5 per cent. solution are used. In extensive cases or with nervous individuals a general anesthetic would be required.

If the palpebral fissure is shortened, a free canthotomy should first be made, extending to the orbital margin to give a free field for dissection. The lid should then be carefully dissected from the cornea, if it is attached thereto, and this can best be done with a Graefe cataract knife. In the course of the separation of the lid from the eyeball and the preparation of a new cul-de-sac the dissection should be made close to the lid and should proceed until the margin of the orbit is reached, if there is much cicatricial tissue present. Unless the dissection is close to the tarsus the lid is apt to appear too thick; this precaution, therefore, is especially to be observed in restoration of the socket for prothesis.

[11] H. W. Woodruff: Ann. Ophth, March, 1903

If the margin of the lid has been destroyed, as by a burn, an attempt should be made to restore it by inverting the part dissected from the eyeball, and by loop sutures passed through it, "hemming" it in a position to secure proper continuity of the lid border. This can sometimes be very accurately done, as in a difficult case of symblepharon I recently had in which two-thirds of the lower lid border changed into scar tissue because of a burn with molten iron, had grown to the eyeball, covering the lower half the cornea.

In preparing such a flap for inversion, care should be taken to make it thin enough by dissecting off the cicatricial tissue with knife or scissors.

When the cul-de-sac has been made of the proper depth and the eyeball is free to move in all directions, the operator proceeds to fashion a prosthetic plate. For this purpose pure sheet lead about 0.5 or 1 mm. in thickness is preferred, for it is easily shaped with scissors, knife and file, and is soft enough to mold into any form to suit the individual requirements. The part that is to hold the graft in the new cul-de-sac may be made of more prominent contour to insure a greater depth at this point. As the piece has been properly sterilized, it can be introduced into the wound to be sure that it will fit. A large circular opening for the cornea is then made with knife or drill and its edges made smooth with a round file. After being cleansed and dried, the plate, held by its edge with light forceps, is dipped quickly in melted paraffin, which has previously been sterilized by boiling.

As has been said before, this paraffin should be hard, with a melting point not lower than 130 F. The thin layer that adheres to the metal can be quickly set by dipping it into cold water, and then it can be repeatedly dipped into the paraffin and into the water until it has an even coating of the proper thickness. The vessel containing the melted paraffin should be in a dish of hot water to prevent congelation; otherwise the layer of paraffin deposited will be too thick and uneven. A very short time is required to prepare such a plate.

A thin Thiersch graft should then be cut from the least hairy part of the arm or leg. It is well to have the graft wide enough so that one piece will answer for each lid and there will not be too much overlapping. The razor that is used for cutting the graft should be in the best possible condition and should be flat on one side, like that used for histologic section cutting. A very little vaselin or soft-soap rubbed on the flat surface of the razor prevents it from sticking to the skin and so insures a more even graft as the surgeon cuts it with short sawing motions. An assistant keeps the razor and graft flooded with warm salt solution.

The graft is transferred to the paraffin plate directly from the razor by setting that edge of the plate which is to rest in the new cul-de-sac against the epithelial side of the graft which is uppermost, and then stroking it into place with forceps or spatula, so that both sides of the plate are covered. The graft is very easily handled, as it adheres beautifully to the paraffin surface, and every wrinkle can be smoothed out or the position can be changed as desired. This adhesion of the graft to the paraffin, preventing the curling of the edges, which is so annoying, and making unnecessary the use of any sutures, is one of the advantages of the method.

The plate now covered with the graft, the raw side outward, is inserted into the new fornix, the hemorrhage, of course, having been checked. The graft naturally comes in contact with every irregularity of the raw surface of the cul-de-sac and should be large enough to lap over on the uncut surface. No sutures or trimming are necessary, for the overlapping edges will either be cast off or can be trimmed off later at the time of one of the dressings, and if care has been taken in fitting and coating the plate and applying the graft smoothly to it all raw surfaces will be covered.

If the symblepharon affects but one lid there will be very little danger of dislodgment of the graft when the operator inserts the paraffin plate, if he first presses it into the new cul-de-sac and then draws the sound lid over it. If both lids are involved it would be better to avoid displacing the graft on one side of the plate by securing it with two or three sutures, which can be passed through the edge of the graft and then through the openings in the plate to the edge of the graft on the other side. This can very easily be done, as the graft adheres so well to the paraffin. It is almost needless to say that during the manipulation of the graft on the plate an assistant should keep it warm and moist with saline solution. In this way both lids can be operated on at the same session.

If a canthotomy has been done, the canthus should be brought together with sutures, and then a moist boric-acid dressing of gauze and cotton should be placed over the closed lids and held in place with an appropriate bandage. Both eyes should be bandaged and the patient kept in bed. The dressing may be changed the next day so that the cornea may be inspected and the eye gently irrigated with a warm boric-acid or saline solution.

If the case is one in which the eyeball is present, the plate is carefully removed at the end of forty-eight hours to make sure that the cornea is uninjured and that the paraffin has not been rubbed off the plate. The graft will be attached by this time, but after gentle irrigation the plate should be reinserted and the eyes dressed as before.

In cases of restoration of the cul-de-sacs for prothesis in which the eyeball is absent, the plate may be left in position for six or seven days, if there is no evidence of infection, and the orbit irrigated through the openings in the plate. At the end of this time it should be removed, recoated with paraffin, if necessary, and reinserted. If the plate used in such a case has been very large, to insure deep cul-de-sacs, it may be necessary to cut it in two to remove it easily, but this can be readily done with scissors along a central line corresponding to the long axis of the palpebral fissure. A smaller plate can be reinserted or the old one can be reapplied by hinging it, that is, making holes at either end of each half and tying them together with strong silk thread. In cases in which there has been extensive contraction of the conjunctiva, such plates must be worn continuously for weeks to prevent shrinking of the new cul-de-sac.

I have operated by this method in eight severe cases of symblepharon, two of which were total, and with uniformly good results. Six of these cases had extensive symblepharon of the lower lid, so that the cornea was partly covered by the adhesion and the eyeball could not be moved. The patients wore the paraffin plate over the cornea with perfect safety and comfort until the graft had firmly healed in place and good mobility was secured. In the cases of total symblepharon there was complete obliteration of both cul-de-sacs, in one of them the palpebral fissure being reduced to a mere slit. In each case operation was done on both lids at one session and the results obtained were such that an artificial eye could be worn. Furthermore, the length of time that has elapsed since the operation, two and one-half years in one case and nearly two years in the other, without noticeably more shrinking than occurred in the first three months after the treatment, encourages me to believe that the result is permanent.

CONCLUSIONS.

The advantage of a plate for holding mucous or Thiersch grafts in place in the fornix of the eyelids is obvious. The advantage of the paraffin plate is that it can do no harm to the cornea. It can be built up as required to fit any conjunctival cul-de-sac that has to be lined with a Thiersch graft. The graft adheres to the paraffin, so that it can be evenly smoothed out on it, and thus perfect coaptation is secured between the graft and the raw surface of the cul-de-sac. To accomplish this the graft should be thin and large enough to cover all raw surface, no sutures being required. With perfect coaptation the graft will have secured a firm hold at the end of forty-eight hours and the plate can be removed for cleansing the eye. In the case of restoration of the socket for prothesis. it may be left in place for a considerable time, for the sac can be cleansed by irrigation through the holes in the plate. If it is so large that there is difficulty in removing it, it can be cut in two and the subsequent treatment continued with a plate that can be more easily inserted.

DISCUSSION.

Dr. Charles H. May, New York, has been so well satisfied with the porcelain supports he has been using, that he has never felt tempted to try any substitutes. He uses porcelain shells of greater or lesser thickness, having the shape of artificial eyes; in fact, they are artificial eyes minus the coloring which is added for cosmetic effect—the blood vessels, iris and pupil. He has a supply of various sizes, including some which are shell-shaped and others which are thicker and hollow, corresponding to the so-called Snellen or reform eyes. Porcelain can be easily sterilized; it is smooth and polished and thus will not damage the cornea (in cases in which the cornea is intact); it is available in different sizes, shapes and thicknesses, and it requires no special preparation.

He thought that the circular opening in the plate, advocated by Dr. Wilder, is an advantage in those cases in which the operation is performed for extensive symblepharon and in which the cornea is healthy, since it admits of inspection of this part of the eye without removal of the graft support. Even in those cases in which there is no cornea to protect, the ability to irrigate and cleanse the orbit through the openings in the paraffin-covered plates seems a very desirable improvement in technic, providing the necessary separation of the lids does not disturb the graft sufficiently to interfere with smoothness in the adhering process. With the porcelain supports, since it is injudicious to remove the shell for six days, the orbit can not be cleansed thoroughly, and only such material as escapes to the edges of the lids and dressing can be removed. It is true the orbit does not present so favorable a seat for infection as does a bony cavity surrounded by venous sinuses and meninges; but the possible danger of such a result ought not to be entirely dismissed, and the patient's temperature should be carefully watched. The openings in the support, advocated by Dr. Wilder, lessen this danger, if a more extended resort to this operation should prove that such a risk really exists.

Concerning the technic of the operation, he is in the habit of making the cavity just a little larger than is desired. The formation of a little recess at the external canthus is very important. A prothesis is inserted which makes the palpebral aperture just a little larger than that of the opposite side; the one selected should fit nicely and easily, and should remain in position without any necessity for external aid. During the time that bleeding is being controlled, the prothesis is removed, placed on a piece of rubber tissue and a pattern cut out one-third larger than is sufficient to envelope the artificial eye; this serves as a guide to the size and shape of the graft. He prefers Thiersch grafts, but is not prepared to say that they should always be used. The Wolff graft is thick and occupies a good deal of space, the defect in the integument is a very considerable one, and there is often some tension and sometimes a little difficulty in the approximation of the edges, and always quite a scar. In one case in which he used a Wolff graft, although he selected a region of the skin devoid of all but the very finest hairs, the latter became thicker, coarser and longer in their new situation, and in the course of a few weeks quite a crop of good-sized hairs presented itself in the newly-formed socket; the thick graft is much more easily handled than the Thiersch grafts.

The graft is next wrapped around the prothesis, with the raw surface externally, in such a manner that the junction of the upper and lower margins will fall in the middle of the anterior or convex surface of the support. If, after insertion, the support stays in nicely so that there is no tendency to fall out, and the socket seems comfortably filled so that the lids can be closed readily, he does not insert any stitches either through the bottom of the cul-de-sac, at the edges of the denuded portion of the socket, nor sutures to hold the lids together. The support if sufficiently large and correct in fit, keeps the graft in close apposition with the raw surfaces. The marginal excesses of the graft slough away. A moist dressing is applied, changed after 48 hours, and daily thereafter; but the support is not disturbed until after 6 days.

He agreed with Dr. Wilder that no sutures are necessary. He has used marginal stitches, and has also employed two sutures through the bottom of the cul-de-sac, coming out just above the supraorbital margin, as recommended by Weeks; but the cases treated without both of these forms of stitches have done just as well as those in which he has used them. The main factor in keeping the graft in place and in having it taken evenly and completely is not the stitches, but sufficient size of the cavity created and ample size and correct shape of the support. In those cases in which there is a globe with clear or damaged cornea and the operation is resorted to for the cure of extensive symblepharon, he is in the habit of sewing the graft or grafts in place by marginal sutures, and then inserting the shell-shaped support. Here also, the success or failure of the operation seems to depend on the establishment of sufficient depth of the fornix and the insertion of a support of adequate size.

Dr. Clark W. Hawley, Chicago, has seen the plates used in one or two cases with very satisfactory results. He has never used the Wolff grafts, but has used a large number of Thiersch grafts and has been well satisfied with them. Some operators make them too thick. He has seen two operations for pterygium fail because the grafts were too thick. The grafts can not be made too thin, especially when grafting on the eyeball itself. The suggestion as to infection through the Thiersch grafts he thought was not well taken. He thoroughly cleanses the field from which the graft is taken so that there is very little danger of carrying infection that way. He has never lost even a part of a graft and so has had no thought of such a thing as infection.

Dr. John E. Weeks, New York, pointed out that it is evident that different men with the same purpose in view, and the same material to work on, will obtain different results. In his opinion there are a number of essentials for the success of this operation. One is that the groove must be sufficiently large and deep; in many cases the external canthus must be divided. Another is that the flap must have attachment to the peritoneal

tissue in order to maintain the depth of the cul-de-sac. Another that the plate must be sufficiently large to carry the graft to the bottom of the groove in case sutures are not employed. Dr. Wilder's plate meets that indication fully. An artificial shield, as made by the men who make artificial eyes, is frequently not large enough and does not carry the graft sufficiently deep. In his opinion a plate which the operator can mold at the time of the operation is preferable, so that a paraffin plate made as Dr. Wilder has made it is a very excellent one. The plate made of gutta percha is also a good one. An advantage in Dr. Wilder's method is that sutures are not necessary. If the Wolff graft is used, sutures are necessary. He has operated on fourteen cases after the method described by him and they have been successful without exception. The earliest case is now seven years old and is all right. A fault with many operations is that tissue fills in from the bottom and the cul-de-sac is obliterated. Another advantage of Dr. Wilder's method is that both lids can be operated on at the same time. That can not safely be done by the method the speaker advocated. One other thing is the prevention of sepsis. The antiseptic precautions should be thorough. If this is well done there is no reason why the operation should not be successful.

DR. S. D. RISLEY, Philadelphia, has resorted to many methods and thinks this will probably be an improvement. Sometimes, however, simpler things work very well. His first attempt was with a celluloid plate, softened by placing it in hot water, and a sheet sufficiently large cut out, with three or four openings through it for drainage. Next he used a thin plate prepared in the same way. He used this to hold the graft in place and also as a shell in very young children where it was not possible for years to wear an artificial eye. On one occasion where he was compelled to resort to something on the spur of the moment, he employed sterilized protective, holding it in place by packing in cotton, and he has never had a case do so well as this one.

One of the important parts of the technic is the treatment the graft receives. These cells are very easily destroyed, especially by efforts to render the graft absolutely sterile. Chemicals that are destructive should be avoided. The physiologic salt solution is the one he always uses. He favors the Thiersch graft and always puts it in place from the razor without putting it into any fluid. Placing one end of the graft in contact with the wound, then pulling the razor away, it spreads itself out as though it belonged there. There is no need to fear its being washed away if the surface on which the graft is placed has been prepared carefully. The readiness with which these cut cells adhere to the denuded surface is remarkable.

DR. C. D. WESCOTT, Chicago, has seen Dr. Wilder operate by this method and vouched for the simplicity of the method as compared with others. He said that the plate can be made of almost any desired thickness by rapidly dipping it into melted paraffin, and manipulating the paraffin with the fingers as it is cooling. The shape of the Snellen can be closely imitated, if desired. The modeling wax of the dentists may be used instead of paraffin. It is a substance of higher melting point than paraffin.

DR. WILLIAM H. WILDER agreed as to the necessity of as perfect antisepsis as can be practiced in this locality, although the tissues here are much more resistant than elsewhere. Grafts will hold in the socket and on the lids that perhaps would not hold elsewhere. The chief advantage urged for this little measure is its adaptability. There is no question about the artificial eye itself furnishing an excellent plate for the graft, but it is essential to have something that can be adapted to the individual case. One of these plates can be made in five minutes and tried to see if it fits the socket. It can be made more prominent at one place than another to suit the individual case. Another advantage is that both lids may be operated on at the same sitting, but the precaution should be taken of making a good wide canthotomy to expose the field to view. Later a canthoplasty can be done.

Diabetic Insomnia.—Hutchinson gives twenty grains of strontium bromid and fifteen grains of antipyrin at night.—*Denver Medical Times.*

THE FETICH OF DISINFECTION.*

C. V. CHAPIN, M.D.
PROVIDENCE, R. I.

Disinfection in this connection refers to that sort which is commonly carried out by health officials after death, or recovery, from contagious diseases. The paper has no reference to that continuous attention to cleanliness—"medical antisepsis" the French call it—which is desirable in the management of contagious cases. This terminal disinfection, if one may so call it, occupies a high place in public sanitation. A reader of works on hygiene would conclude that disinfection is held in equal esteem with isolation, or is perhaps of even more importance, for it is sometimes expected to work wonders in the prevention of disease where there has been no isolation, as, for instance, the official disinfection after a case of tuberculosis when for years there may have been no attempt on the part of the patient to prevent the infection of others.

OFFICIAL DISINFECTION.

Official disinfection costs money and is annoying. Its only excuse is that it is believed to be an important factor in preventing disease. But is it an important factor, and is its practice based on good evidence of its necessity and value? It is to be feared that it is not. We do not disinfect because the utility of the process has been demonstrated, but because of precedent and authority. There can be little doubt that disinfection had its origin at a time when disease was believed to be the work of demons. Burnt sacrifices and fumigations with aromatics were among the means employed to appease the supernatural powers. The early practice of medicine was confined to the priesthood, and the final cleansing of the sick was largely a religious ceremony. This cult of purification by fire and smoke and libations has continued even to modern times. The attempt to give it a scientific basis is an afterthought.

REASONS FOR DISINFECTION.

Several arguments are advanced by the advocates of disinfection in support of the practice. Disinfection is necessary, it is claimed, because the virus of the disease becomes attached to material things such as clothing, books, toys, furniture and the walls and woodwork of rooms. On these things, it is said, it retains its life for weeks and months, and these infected things are, therefore, a very important factor in the extension of the contagious diseases.

That this is so is believed because numerous cases are on record in which infected things are assumed to have caused sickness. Reports are often made of diphtheria due to exposure in a room which had not been disinfected or due to contact with infected books or playthings. The virus of scarlet fever is supposed to be particularly tenacious of life, and we hear of cases due to the bringing out of infected clothing or furs which had been put away months or even years before. While accounts of such cases are often enough found in medical literature, they are, even if true, far from proving that such infected things are a really important factor in maintaining our common contagious diseases. Now, just here, I wish to make myself perfectly clear. I would not, in the present state of our knowledge, for a moment deny that clothing, books and even a room itself may be infected and may remain so for a considerable time, and then give rise to a fresh outbreak of disease. What I do claim is that reports of such modes of infection are rarely well authenticated, and even if it is admitted that such infection occasionally takes place there is no evidence that this is a factor of any moment in the extension of the contagious diseases, while there is a great deal of evidence that it is a factor of no consequence at all.

TRANSFERENCE OF DISEASE.

To return to the value of the evidence of the specific instances narrated of the transference of disease by infected clothing, bedding, toys, books, letters, etc., it is well to recall in this connection how firmly was established the theory that yellow fever was often transmitted by fomites. Any one who questioned this was laughed to scorn. The proof of it was felt to be conclusive by almost everybody. To sleep in a bed lately occupied by a yellow-fever patient would have been thought to be suicidal. Now we know that this has been done with impunity, and that clothing, bedding and letters are never carriers of the yellow-fever virus. Perhaps it would be well, then, to question whether or not an infected room really does cause diphtheria in its occupants, or a woolen coat transmit scarlet fever, or toys act as the bearers of measles. In most of the cases of alleged infection by fomites the fact is not proven at all; at best it is a possibility merely, not even a probability, and certainly far from a demonstration. The majority of cases of contagious disease can not be traced to their origin. Because a certain case develops soon after exposure to a supposed infected article is no proof that it was due to such exposure. As will be shown later, direct exposure to infected persons is the probable source of the infection in most cases of contagious disease. Unless this source of the infection can be fairly well excluded, it is merely an assumption to attribute the infection to things. A more critical examination of these cases would eliminate most of their value as evidence. After all, instances of apparent infection by fomites are rare. In my own experience of 22 years as health officer I have met with few of them, even in the earlier years of my practice, when I must confess I looked for them more carefully than I do now, since I have become satisfied of their unimportance. Doubtless all health officers will agree with me as to the rarity of cases in which it appears probable that fomites are the source of infection. Certainly no one could develop by induction, from their frequency, the theory that the contagious diseases extend chiefly in this way. It will not be claimed that the health officer practices disinfection because compelled to it by the frequency with which cases of fomites infection are brought to his notice. It is done for other reasons.

Probably one reason why so much importance is attached to thing infection is the large amount of discussion which is given to the question of the vitality of bacteria outside the body. Everybody has heard that anthrax and tetanus spores live for years, and, though it is generally recognized that most of the common disease germs do not belong to the spore-forming class, this great vitality of these exceptional types has had its psychologic effect. Bacteriologists have been very apt to report instances of maximum vitality of the organisms of pneumonia, diphtheria, plague and the like, but it is generally forgotten that these are the exceptions, and the impression remains that most of the bacteria given off from the sick retain their vitality and virulence for a long time, which is certainly not the fact.

But undoubtedly there is another and chief reason why the belief has become so well established that the virus of disease remains long attached to things, that these fomites are a most important source of infection; and that the contagious diseases can only be successfully combated by terminal disinfection. As was before stated, it has rarely been possible to trace more than a small proportion of cases of contagious disease to direct contact with others. Even in country places cases are constantly appearing without any visible connection with a previous case. In cities it is still more difficult to trace direct exposure to the sick, and so far as can be determined by routine examination the majority of cases of scarlet fever and diphtheria appear to arise spontaneously, or sporadically, as it was formerly called. Even in smallpox, which owing to its marked eruption and comparative rarity is easier to trace than almost any other disease, a large portion of cases appear to have no connection with previous cases. To explain the origin of these cases has been the chief problem of sanitary science. At one time it was believed by many that the virus of most of the contagious diseases could develop outside of the body. Hence the filth theory of disease, which, although now entirely discredited, still has great influence, even among sanitary officials.

THE SPECIFIC VIRUS THEORY.

The hypothesis which next appealed to workers in this field was that the specific virus, though incapable of growing outside of the body, could yet retain its vitality for a considerable time, and, attached to various articles, be carried unnoticed to great distances. It must be admitted that this is a very natural and reasonable hypothesis and is supported by many of the findings of bacteriology, and by certain clinical observations. A dozen years ago it was really the only working theory that we had. Of course, if its probability is admitted, disinfection must necessarily follow. This, I take it, is the true reason why for so many centuries disinfection has played such an important part in preventive medicine. It was the only means for controlling that mode of infection, which appeared to be the principal factor in the maintenance of the contagious diseases.

ORIGIN OF DISINFECTION.

Disinfection had its origin in superstition, and its practice so partakes of the character of magic art that it catches the popular fancy. Even if the health officer does not disinfect, the infected family is quite likely to sprinkle a little sulphur on the stove, or place a saucer of chlorid of lime behind the door. Thus unconsciously do we follow the customs of our remote ancestors who exorcised the demon of disease with incense and incantation. Here we have another explanation of the vogue of disinfection.

SCIENTIFIC ARGUMENT IN FAVOR OF DISINFECTION.

Let us now examine into the principal scientific argument in favor of disinfection, i. e., that infection is spread chiefly by things. As was before stated, this theory was the outcome of the attempt to explain the origin of that vast number of cases of contagious disease which could not otherwise be accounted for. But within the last dozen years a multitude of facts have come to light which renders this theory unnecessary. It has always been recognized that mild and atypical cases of contagious disease are occasionally seen. Scarlet fever without eruption, mild sore throat diphtheritic in nature, and walking cases of typhoid were mentioned by the older writers; but they were not believed to be common, and little account is taken of them in the textbooks. To-day the majority of physicians are skeptical about the diagnosis when they see an almost afebrile scarlet fever with slight, fleeting rash, or diphtheria without exudation and the patient not confined to the bed; yet those who have studied these diseases most closely know that the mild, atypical cases are extremely common. Even in smallpox, a disease with more characteristic symptoms than any other, mild, unrecognized cases are very numerous. If one examines the reports of health officers of the past few years, it will be found that the frequency of these mild cases is dwelt on, and to them is attributed the origin and maintenance of most of the local outbreaks. The report on typhoid fever during the Spanish war indicated that mild, unrecognized cases were twice as numerous as the recognized cases. In investigating this disease in a small rural community Koch found scores of cases which the attending physicians failed to recognize, or to which no physician was called. Instance after instance is recorded in which a mild sore throat has been the starting point of an outbreak of diphtheria. In Hartford, of 2,038 apparently benign sore throats found in children at school, 29 per cent. were shown to be true diphtheria. The English, who often isolate as high as 90 per cent. of their recognized scarlet fever cases in hospitals, and nevertheless continue to have as much of this disease as we do, attribute their failure to control the disease to the existence of so many mild, unrecognized cases. In fine, we now know that there is a vast number of atypical, unrecognized cases of contagious disease, sometimes exceeding in number the known cases.

CARRIER CASES.

We have learned that there is still another factor to be reckoned with. It is now well known that the pathogenic bacteria often grow in human beings without producing any symptoms of the disease. After recovery, the specific bacteria may continue to develop for weeks, months, and even years. Not only that, but they are found also in persons who have never been sick at all. These are what the English call "carrier" cases and present no symptoms. They are even more numerous than the mild cases of illness. Such carriers have been found for diphtheria, influenza, cerebrospinal meningitis, typhoid, cholera, the plague, and many other diseases, and the wide distribution of the pneumococcus is known to everybody. In the protozoan diseases, as malaria, trypanosome diseases and Texas cattle-fever, individuals often carry the infection in the blood and show no symptoms. These facts receive scant recognition in most text-books, even those on bacteriology, and are entirely ignored by nearly all writers and lecturers on clinical medicine and sanitation, yet they are of the utmost significance. In these mild cases and living "carriers" we have the real source of contagious disease.

BACTERIOLOGY.

What does bacteriology tell us about this matter? The direct evidence as to the infection of things is scanty. It must be admitted that there has been very little investigation of this question, although it lies at the basis of sanitary theory and practice. Examinations made in Providence, and by Hill, in Boston, show that diphtheria bacilli are rarely found, even on objects most likely to be infected by the patient. Tubercle bacilli are more tenacious of life than most common bacteria, yet search made for them on floor and walls, where they are most likely to be expected, usually fails to reveal them. It is not easy to find pathogenic bacteria outside of the body. While it is true that bacteria, especially certain resistant kinds, like the tubercle and typhoid bacilli, may occasionally live for some months when removed from the body, it is nevertheless true that all non-spore-forming pathogenic bacteria tend to die off, and that quite rapidly, when so removed.

This whole question may be summed up very concisely. Which is the more likely to be the chief factor in the extension of contagious disease: inanimate objects hypothetically infected with dying bacteria, or living and moving human beings who are continuously throwing off living bacteria? It must be admitted that fomites may spread disease; but, if we reflect how unlikely infected things are to be brought in contact with people and how great the chance of human beings coming in contact with each other, it seems very unlikely that fomites can have appreciable effect in the spread of disease.

FUTILITY OF DISINFECTION.

If then, as all evidence tends to show, contagious diseases usually extend by means of pretty direct contact between the infected and non-infected, and transmission by fomites has little influence on such extension, it follows that even the most thorough disinfection will have little effect in checking these diseases. There is certainly no rational basis for making it such an important feature in public health work, and holding it of equal value with isolation.

Another thing to be borne in mind in connection with this subject is that a good deal of disinfection does not disinfect.

Until eight or nine years ago sulphurous anhydrid was the chief disinfectant, and this is now considered to be entirely unreliable. Then formaldehyd came into use and at first most of the disinfection with it did not accomplish more than the sulphur. Even now a great deal of formaldehyd disinfection is inefficient, and at the best only exposed surfaces can be disinfected. As the larger part of the clinical evidence of the value of disinfection dates from a time when the process was very imperfect, the value of that evidence is much impaired.

In Providence we have been making a practical test of the value of disinfection by omitting it entirely in some cases. It seems useless to disinfect an apartment unless we can be fairly sure that its occupants are not propagating the germs of disease. In diphtheria we can have no reasonable assurance of this without getting at least two negative cultures from the nose and throat of every member of the family. To require such cultures is impracticable. Disinfection, however, is refused after diphtheria, unless the above-named reasonable conditions are met, which very rarely happens, or unless it is especially requested after a death. During the last year the warning card has been removed 258 times without disinfection, and there has been a recurrence in the family within two months in four cases, or 1.55 per cent. In 87 instances in which disinfection was practiced during that period or a few months preceding it, there was a recurrence in 2.3 per cent. of the cases. The total number of cases of diphtheria fell, however, from 780 in 1904 to 562 in 1905.

It may be asked: What objection can there be to disinfection even if it is not so important as has been thought? Aside from the question of expense, which is by no means unimportant, there is a decided objection. The confidence which the public has in the efficacy of disinfection is the greatest hindrance to the development of better methods of handling disease and guarding against infection. To practice strict personal cleanliness, not only in the presence of contagious disease but at all times, is the sole mode now known in which the unrecognized cases and the "carrier" cases can be guarded against. The public, and even the medical profession, refuse to believe in infection in well persons, but cling to the old notion that it is things, not persons, that are to be feared. And they will cling to this view so long as health officials lay so much stress on their official disinfection. Many a time a family has lived for months with a consumptive who has taken no precautions about his sputum, and after his death has promptly asked to have the house fumigated. The expiatory sacrifice of disinfection is believed to atone for every sanitary sin. It is our duty to teach that hygienic salvation can only be attained through the good works of personal cleanliness. As the surgeons have given up antisepsis for asepsis, so the health officer must substitute cleanliness for disinfection.

SUMMARY.

As a brief summary of the argument and the conclusions to which it leads, it may be said:

1. The pathogenic bacteria tend to die rapidly after discharge from the body.
2. There is very little bacteriologic evidence that things remain long infected, and, therefore, contact between the non-infected persons and the infected things must be very direct and very close in point of time if the things are to transmit the infection.
3. Clinical evidence of the necessity for disinfection is wanting.
4. The true explanation of the spread of contagion is the great number of unrecognized, atypical and "carrier" cases.
5. Infected persons, not infected things, are to be feared.
6. Disinfection, that is, official disinfection as a final precautionary measure, has little value in preventing the spread of the common contagious diseases.
7. This sort of disinfection is a powerful factor in preventing sanitary progress, by encouraging belief in discredited theories.
8. While it is by no means advisable to abandon disinfection entirely, it should not be made so important a part of public health work, and should not be insisted on unless it is practically certain that no member of the household remains infected, and should be refused when it is probable that any member of the household is so infected.

DISCUSSION.

Dr. Clarence L. Wheaton, Chicago, declared that if we accept the theories advocated by Dr. Chapin, the germ theory must be overthrown. Dr. Wheaton said that it has been demonstrated by bacteriologic examination that the dust on the walls of rooms occupied by tuberculosis patients contains, at times, bacilli; and that it has been possible to make cultures of these germs, proving it absolutely. The same, he believes, is true in cases of diphtheria. Now it would be almost malpractice, he declared, to leave these homes without proper disinfection.

Dr. W. F. Morrison, Spokane, Wash., declared that if Dr. Chapin's ideas of sanitation and disinfection are adopted, we will very soon be followers of Mother Eddy. As a health officer of four or five years' experience, Dr. Morrison said that he has had quite a good deal to do with contagious diseases. He has seen the spread of contagious disease more frequently when disinfection has not been performed than when disinfection after the good old-fashioned method of first cleaning the body, then cleaning the clothes and then disinfecting the house goes hand in hand; and if the clothes are left unwashed, uncleaned and undisinfected, and only the individual is cleaned, the individual may be clean, but the house from which the individual comes (if there is any sense in the germ theory of disease) is still full of living germs; and if one goes into that house and stays long enough and is not immunized he will get the infection. Not everybody gets any infection; thousands of people escape who are immune; thousands of people are immune to everything. Every day of our lives we see the most filthy people escape all forms of disease. Among the indigent in obstetric work physicians see the most abject filth, and yet comparatively little contagion arises from it; and women get up in three or four days and go to work apparently well. In Dr. Morrison's opinion we must not only disinfect the patient with soap and water, but must also disinfect the house from which the patient comes by some approved disinfecting agent. The things must be combined. Dr. Morrison asked if a surgeon who washes his hands with water and makes them as clean as he can, not using approved disinfecting agents, in preparing for a surgical operation would be clean or fit to operate on a patient. If so, the germ theory of disease, he said, is of no value whatever. Providence, he said, has been exceedingly kind to the people of Rhode Island, but Dr. Morrison does not believe the rest of the world can safely follow their example at the present time with the present knowledge.

Dr. S. A. Knopf, New York, declared that there is a happy medium, that we need not go to excess, but we should clean the patient and clean the room. In regard to tuberculosis, he said that he could not accept the idea that the patient is more of a danger to his fellow men in the first stages of the disease. Dr. Knopf thinks that the patient who is up and about, expectorating everywhere, is more of a danger than the one confined to his room, who is only a danger to the few people who are in that room. Dr. Knopf declared that he knows of a number of cases in which the walls have been infected through careless expectoration and in which people who have moved into these rooms without having them previously disinfected have contracted the disease. In his investigations of prisons Dr. Knopf has found prisoners who have contracted tuberculosis in cells where other prisoners who had suffered from this disease had remained for a number of years. Simple whitewashing was not enough to do away with the infection. Examination of the dust from the walls showed the presence of the tubercle bacilli. Dr. Knopf said that he is not a specialist in typhoid fever, but he would not wish to have the linen of a typhoid patient put with other linen without previously disinfecting it. Certainly he would never use the handkerchief of a tuberculosis patient, even though the patient had never expectorated in it, but simply wiped his nose and mouth with it. In tuberculosis, Dr. Knopf said, we must not forget the rôle of flies in the transmission of the disease. The ordinary house-fly will take up tuberculosis matter and deposit its excrement on the walls, and it has been demonstrated, Dr. Knopf said, that the excrementitious matter from flies which had been in a room with tuberculosis patients when injected into animals led to tuberculosis. Therefore, he said, physicians should not teach that disinfection after death is not just as important as prevention while the tuberculosis patient is alive.

Dr. H. D. Holton, Brattleboro, Vt., said that in the exposure of a hundred people to any contagious disease perhaps not more than forty would come down with it. Why? We do not know. We say their systems were not susceptible at that time. It is very difficult to trace the source of contagion. We do not know, a great many times, where scarlet fever comes from. Dr. Holton sometimes finds out months afterward from some slight circumstances, but he has seen repeated evidences of its contagiousness. He carried it home, he believes, to his own little girl many years ago. He was visiting a man, and a little girl was playing with some toy acrobatic men; she was dovetailing them together and Dr. Holton assisted her and handled them while talking to the man. He went home and his little girl urged him not to go into the office, as his supper was ready, so he picked her up and carried her into the dining-room. In five days she was down with scarlet fever. On investigation it was learned that these toy acrobatic men had been used by the other child to amuse her while recovering from scarlet fever. Dr. Holton has always believed that taking these toys and gathering from them the loose collections in the dovetails, which, under the microscope, proved to be epithelial scales, was the source of his daughter's scarlet fever. Contagion occurs in different ways. Dr. Holton believes that it comes from walking cases of diphtheria, scarlet fever and measles. He has seen these patients without any eruption at all, and yet they communicated the disease. We see typhoid-fever patients walking around; there is no question about this. The first case of typhoid fever that occurred at Chickamauga Park came from a soldier from Vermont, who enlisted from a town where there was polluted water and typhoid the year round. Dr. Holton believes that the soldier carried that germ in his body; by exposure and changed methods of living he developed typhoid fever. Not every person who, having tuberculosis, is not careful about sputum communicates tuberculosis. We know that it may be communicated in just that way and that not to exercise care and caution would be criminal. We used to see a wife whose husband had died with tuberculosis and who had nursed him through his illness develop the dread disease. Shall we say that it is not demonstrated that the disease was communicated to this devoted wife by bacilli from the sick husband? If so, Dr. Holton said, we must give up all the theories that we have held. It is possible, he said, that Dr. Chapin did not really mean to give us all the ideas that we absorbed. He is very forcible in expression and his hearers may have taken a little more than he intended.

Dr. J. N. Hurty, Indianapolis, said that he still believes in disinfection. He can not throw it aside. It seems to him that beyond doubt some diseases are carried by fomites. He holds to the belief that scarlet fever may be so carried, and he believes that typhoid fever may be carried by infected clothing. It should be disinfected. Disinfection carries with it a psychic effect which is worth much. He declared that disinfection may be relied on with too much confidence. An individual or a head of a family might say, "My house has been disinfected and I need not be clean." Again, disinfection might bring calmness of mind and satisfaction with conditions, which is not without worth. Dr. Hurty would prefer to have clothing disinfected, even in yellow fever, not to stop the disease, but to satisfy the desire of the mind for perfect cleanliness. Although he knows perfectly well the method of transmission of that disease, still he said that he would prefer to have yellow-fever clothing disinfected. In reference to Dr. Chapin's remark about the tendency of pathogenic organisms to die, Dr. Hurty said that he was taught that the unicellular organisms are immortal. They do not die; they are destroyed in untold millions by various agencies, such as light, air and disinfectants, but their duration of life is not limited by the needs of the species, as in the case of multicellular organisms. He said that this paper will make us think on this subject, and by thinking and by study we will finally arrive at a correct solution of the problem of disinfection. He said that he will now study this subject with new zeal and with greater earnestness.

Dr. A. D. Lake, Gowanda, N. Y., said that the departure of Dr. Chapin from our accepted belief has been so decidedly radical that it seems to him that Dr. Chapin must more thoroughly substantiate his position before he can ask others to agree with him. To take his view of the matter is to revolutionize all of our long and well-established ideas of the value of disinfection. That disinfection is most potent in its power to destroy disease germs was, perhaps, first illustrated in the history of the plague in London. This terrible disease hung like a pall over the city for many months and thousands died therefrom. In the midst of its devastation occurred the great fire, which swept away one-fourth of the buildings of the city, and through this thorough disinfection the further extension of the epidemic was prevented. It was probably the only means, in those days, whereby the awful mortality could have been controlled. As an illustration of the danger of infection from contaminated clothing, Dr. Lake mentioned the following incident: About three years ago a case of scarlet fever occurred at the Thomas Indian School, where about 150 children are maintained by the State of New York. The first patient, a girl, had been taken from another institution, about thirty miles away, where she had been retained for a short time only. It was learned that just previous to her stay there some cases of scarlet fever had existed at the same institution. The disease developed three weeks after her arrival at the Thomas School. It was found that about a week before the attack began some clothing was sent her from the other institution, and a dress which had been worn by a girl who had died of scarlet fever was included in the bundle. This dress was given to her and she wore it at the time she was taken sick. It is well to state that this dress had been hung in a closet and forgotten when the other garments were disinfected. This one case, it seems to Dr. Lake, settles the question of the importance of disinfection and the danger of conveyance of disease through infected clothing.

Dr. D. M. Totman, Syracuse, N. Y., declared his belief that Dr. Chapin is dealing a great deal in theory. Dr. Totman said that he was attending a child who had a very bad throat. He diagnosed the case as a possible case of diphtheria. This was before the certain methods of diagnosis of the present day. He took great care for a few days and kept entirely away from his children, as he always does in such contagious diseases as diphtheria or scarlet fever. Suddenly the child apparently recovered without any other trouble. He saw the child and it appeared perfectly well in the afternoon, about 5 o'clock, and he believed that he had been mistaken about the case and that it was not diphtheria. He put on his overcoat, buttoned it up and went home. He went directly to the room where his little girl was, took her in his lap, opened his coat, held her and kissed her. In five or six days she came down with a typical case of scarlet fever. It was a seven-days' wonder to Dr. Totman how she could have contracted it. In the proper time (five or six days) his other little girl came down with the same disease. She was very ill. He looked for a rash. His daughter had a little rash on the back of her neck only. He visited the first child and found the desquamation of a typical scarlet-fever case of three weeks' standing. Dr. Totman said that nothing can ever convince him that he did not carry that scarlet fever in his clothing.

Dr. Wallace Clarke, Utica, N. Y., asked Dr. Chapin to define cleanliness. He asked if it is the strong, stalwart scrubwoman, with her pots and pails and liquid disinfectants and soap and water, or is it the introduction into the room of something that will reach every particle of the room as no liquid disinfectant will. He said that this question came up three years ago before the sanitary convention of the State of New York, when the health officer of Rochester introduced exactly the same idea. With regard to cases, he said that he had just been through an epidemic of scarlet fever, lasting two and a half years; it is not over yet. There have been over a thousand cases. In one institution where the officials struggled against scarlet fever very strongly they finally conquered it. Then the building in six or seven weeks was thrown open to visitors again to come and see their children. In the meantime the epidemic was prevailing in the city. Within a short time there was a repetition of scarlet fever in that institution. Visitors were again shut out and again it was got under control and the building thoroughly disinfected, as it was after the first attack. No one was allowed to visit the building, and the inmates were in no way allowed to go out or to communicate with people where they might catch the disease; still, in about two months the disease reappeared. Here was another faulty disinfection, apparently, or a useless disinfection. The cause was looked for and it was found that clothes which had been used in a scarlet-fever ward had been put in a hamper and put in a closet in the laundry. That closet was not reached in any way by disinfection. Missing those clothes, the laundry woman remembered they were in there and sent one of the boys to the room to take the clothes to the laundry. That boy developed scarlet fever seven days afterward. Dr. Clarke would ask Dr. Chapin as to the time limit when he would admit outsiders into a room where there had been, say, scarlet fever.

On the subject of disinfection Dr. Clarke said that formaldehyd is his favorite agent, but he finds that a large body of men do not know how to use it properly. They disinfect the houses and neglect the kitchens, and they forget to disinfect pet animals in the house, and then they claim that disinfection is complete. When a house has been disinfected Dr. Clarke disinfects every one in the kitchen; finally the last person disinfects the kitchen, some outsider disinfects the last-named disinfector and the disinfection is complete—and that in the presence of a great deal of moisture. One may have a disease in a house—scarlet fever or diphtheria—and not disinfect, and have no repetition of the disease. But Dr. Clarke declared that 91 per cent. of individuals are immune to measles and 33 per cent. to scarlet fever. All physicians know that the mere non-disinfecting of the house shows that immune people as a rule have invaded that house afterward or they would have acquired the disease.

Dr. Charles S. Williamson, Chicago, in regard to the question of disinfection, advised looking at the disease in the same light as tuberculosis, and referred to the experiments of Cornet. In these experiments he said that we know that the infection comes from only one source: the expectoration of some infected individual. Now if a patient has been living in a room and has been coughing, even if he has not been deliberately expectorating, little droplets of sputum may be deposited over the entire room, even to the ceiling. If then, Dr. Williamson said, disinfection is unnecessary, we must admit that this whole area is unaffected and incapable of transmitting the infection; yet many experiments have demonstrated that Pullman cars, cabs, etc., are infected in a large number of cases. Dr. Williamson called attention to the fact that all physicians are coming to recognize the importance of house epidemics of tuberculosis and said that these can occur in only one way. He mentioned some of the conditions in Chicago: Some tramp gets tuberculosis; he goes to a lodging house and expectorates over everything. When investigating instances of tuberculosis it is found that certain houses produce overwhelming numbers of cases. They are not borne in and wafted from the windows; they did not come down from heaven; they are infected by that particular area indirectly from that particular patient. Dr. Williamson said that this is not a matter for academic discussion; it is the most important thing that physicians have to face. He said that for the safety of the people it is necessary to disinfect these houses. When disinfection is improperly done he said that it is usually the fault of the politician who does it. He declared that negative results can be explained by the fact that a great many health officers go through the thing perfunctorily. The disinfection is not carried out in the spirit nor even in the letter. Dr. Williamson said that he tells his patients that he will attend to the disinfection and that they are not to turn it over to the health officer. Under these conditions the danger of contagion, he believes, is brought down to a minimum. He said that seven years ago he had the opportunity of assisting in a large number of bacteriologic experiments on dust collected from different pavilions in the same hospitals. It was found that in the surgical division, where a large number of infected cases had been harbored, but where good asepsis and disinfection had been carried out, the infective quality of the dust was very slight. In other words, injection into guinea-pigs, rabbits and white mice in a considerable number of cases did not produce infection; but in the medical ward (and in this particular hospital it was done to emphasize to the medical people the necessity of disinfection) a perfectly overwhelming amount of infectiousness was found in the dust; it was found also that almost every animal inoculated died from streptococcus infection, pneumococcus or miliary tuberculosis. No amount of sophistry can gainsay results of this kind, because they are definite and clean-cut. Somebody will say no patients there took any disease. It is not known that in this particular medical ward some poor fellow who was convalescent did not go out and die of tuberculosis that he had acquired there from the dust. It is known that the dust was there and that it was capable of infecting animals with tuberculosis, and, therefore, probably capable of infecting man. All the negative evidence does not prove anything at all; it is the positive result which counts

Dr. G. F. Patton, New Orleans, said that it has been his fortune to be in the forefront of the battle in all the yellow-fever campaigns in the section where he lives. He began that service under the régime of the Louisiana State Board of Health in office in 1877. The disinfection of that day, he said, might well be styled fetich worship. It consisted in walking backward and forward with a garden sprinkling pot and scattering carbolic acid solutions on the suspected fomites. The system of maritime quarantine then in force actually invited an invasion of yellow fever by disregarding the incubation period of the disease and trusting blindly to disinfection with carbolic acid, after which hundreds of passengers not more than three days from Havana were admitted to New Orleans up to the beginning of June without any detention for observation. Dr. Patton said that while we all agree in condemning idolatry, there is no one who will seriously propose that the human race shall throw aside all forms of religion because some of those forms savor of fetich worship. The majority of physicians are convinced of the utility of disinfection in dealing with certain infectious diseases. Let us, therefore, he said, accept the logic of the situation as being simply this: that everything connected with disinfection that consists of useless formality be thrown to the winds, but that we can not afford to forget or to ignore the fatal lessons of the past as regards the conveyance of such diseases as erysipelas, diphtheria and scarlet fever by fomites. The evidences of such transmission are too overwhelming and we can not get around them by argument. Dr. Patton said that there is common ground on which others can meet Dr. Chapin. Though all physicians can not accept the doctrine which he advocates *in toto*, still they will agree that the fetich of disinfection which has held the medical profession in bondage for so many years, and has led to untold disasters, is now a thing of the past, and that henceforth our efforts will be to apply disinfection strictly in accordance with the revelations of modern science. We have got rid of senseless disinfection in dealing with yellow fever. That fetich is overthrown, Dr. Patton said, and he is a convert to the doctrine that the disease can be conveyed only by the stegomyia mosquito. We still have with us all the time such diseases as scarlet fever, diphtheria and erysipelas, and we can not get around the fact that they seem to be carried by fomites. Therefore he considers it our duty to act on that belief until very much stronger argument to the contrary is brought forward than has yet been presented.

Dr. Seneca Egbert, Philadelphia, said that in spite of the fact that he does not believe that Dr. Chapin has convinced any one that disinfection is not wise nor necessary, he feels that the doctor has some of the logic of the question on his side. Prophylaxis includes all the methods that may be used to prevent disease, and we can divide the work of prophylaxis into two parts: disinfection, which gets rid of the exciting causes of disease, and that greater function, sanitation, which has to do with the removal of the predisposing conditions. Dr. Egbert declared that Dr. Chapin has in his favor the fact that physicians are doing a great deal of harm in giving the public the idea that disinfection is the thing of most importance in our efforts to eliminate infectious diseases. Physicians still have a great deal to do in teaching people that they can increase their own personal vital resistance by the many ways of sanitation, and that they can thus very greatly lessen the incidence of infection and the consequent number of cases of disease. Dr. Egbert does not agree with Dr. Chapin that it is wise to do away with sanitary disinfection. He believes that every infected place should be thoroughly disinfected; and that word "thoroughly" means a great deal, and a lack of thoroughness covers a multitude of sanitary sins. Though physicians do not accept Dr. Chapin's ideas as regards the wisdom or advisability of doing away with disinfection, they ought not to lose the idea that the importance of sanitation should be impressed on the public and that every means should be used to educate the people to increase their vital resistance and to make themselves immune. Dr. Egbert said that he feels from his own experience that the laity certainly (and sometimes even medical students) do not get that idea from us as forcibly and persistently as they should.

Dr. Charles V. Chapin, Providence, R. I., explained what he meant by "cleanliness." In some of the Paris hospitals for a few years past they have been treating cases of scarlet fever, diphtheria, measles, smallpox, in what is practically the same ward. The same nurse has gone to a case of scarlet fever and then to a case of diphtheria and then to a case of measles. They have done that without the disease extending from one to another, except in a very few instances—far less often than occurs in most contagious hospitals. That is done by the nurses practicing, as they leave one case and go to another, the same sort of personal cleanliness that surgeons practice in their work. Medical antisepsis is what is needed in the care of contagious diseases. Dr. Chapin wants all people to treat contagious disease exactly in that way, and he never can get them to do it so long as they believe that they can treat it as carelessly as they please, and when they get through call on the health officer to fumigate and thus stop off all sources of danger. He thinks that the psychic effect of disinfection is wholly bad.

He said that instances (usually one) have been mentioned in which it seemed that a disease was transmitted by clothing or some other inanimate object. Dr. Chapin said that he did not deny that every single one of those cases referred to was caused in just exactly that way, but he would be entirely justified in doubting it, because no one presented any stronger evidence than the physicians who mentioned such cases in connection with yellow fever, and we now know that there was not the slightest basis of fact in any single one of those cases. The sole question we have to consider, he said, is whether or not that mode of dissemination of disease is an important factor in the maintenance of contagious disease in the community. He does not think that the advocates of disinfection have substantiated their theory that fomites are an important factor. This subject can only be settled in a statistical manner, and the collection of statistics is very difficult. There is no question but the chance of transmission in the ways suggested is greater in tuberculosis than in any other of the common diseases we have in this country. Dr. Chapin said that physicians often hear about cases of tuberculosis contracted in an infected house, but he has never seen that any infection in the lung diseases comes from the house, except in the living beings who are the occupants of the house. The men who advocate this theory of transmission by fomites should present evidence which is unimpeachable to support their view.

Dr. Chapin said that he believes in disinfection when there is reason. He thinks that we must treat different diseases in different ways. In his paper he said he referred chiefly to the routine work of the health officer in this country, and especially in the common diseases, such as scarlet fever, diphtheria, tuberculosis, typhoid, measles. He thinks that we should have disinfection in certain cases. In pandemics, suppose a person has been sick in a house for some time; no care has been taken; the patient is removed by death or otherwise; now if another and well family should come into that house he thinks that the house should be disinfected—not by the disinfection of sulphur and formaldehyd, but by elbow grease and soap and water. Even without this disinfection he thinks that the danger of infection of the second family is very slight. However, nine-tenths of the disinfection done to-day after tuberculosis is, he maintains, where the patient has been sick with the disease and has remained in the family until removed by death, and the family is going to remain right in the same house; no precautions have been taken during the long course of the disease and they expect fumigation or disinfection by the health department is going to help them to atone for all past sins of omission. He said that it is wrong for him to do it and to confirm them in the wrong idea. Again, he is called on at times to disinfect for tuberculosis when the greatest precautions have been taken over a period of months or years. It seems to him that there is no use for it, that it is possible for a tuberculosis patient to live in a room with others and to work with them and not to infect them if he will only take care of his sputum. If that is true, there is no necessity for disinfecting a house which the patient has taken care to disinfect, or, rather, not to infect. Practically, Dr. Chapin said, when the danger of infection is greatest there are very few cases in which disinfection is of the slightest good.

In diphtheria there is no question but that in a majority of cases it extends by means of bacilli in the throats and noses of well people or of convalescent people, and it is perfectly absurd and wicked, he said, to disinfect a house where there has been diphtheria unless we are very sure that the people who live in the house are no longer infected. It is possible for us to learn whether or not the people are infected. Isolation can not always be maintained in diphtheria until the physician is sure of non-infection; and, therefore, in Providence the plan of not disinfecting simply as routine was adopted. If any family wants disinfection they have to subject their throats and noses to two or more tests by culture and show that no bacilli are present. Dr. Chapin believes that the common contagious diseases are almost entirely carried by the direct contact of sick persons and infected well persons with the well; that is, by persons and not by things; and if that is so, disinfection of things, no matter how well carried out, can have no appreciable effect in checking the spread of these diseases. He believes that if to-day in the United States disinfecting after scarlet fever, diphtheria and tuberculosis should be stopped, it would not have the slightest effect on the prevalence of these diseases.

STUDIES ON PHAGOCYTOSIS.*

D. H. BERGEY, M.D.
Assistant Professor of Bacteriology, University of Pennsylvania.
PHILADELPHIA.

The studies of Leishman, of Wright and Douglas, of Neufeld and Rimpau, of McFarland and Engle, and of others, have opened up a new field of investigation for the elucidation of the problem of the mechanism of immunity. The experiments that have been reported thus far have dealt almost entirely with the opsonic powers of the blood serum against staphylococci, streptococci and pneumococci, and the observations have been made exclusively on the phagocytic powers of the polymorphonuclear leucocytes, or the microphages of Metchnikoff.

It seemed desirable to ascertain whether the opsonic power of the serum was efficacious against other classes of micro-organisms, and also whether the macrophages of Metchnikoff participated in the phagocytosis. Metchnikoff himself states that in the resorption of animal cells in general it is especially the macrophages which intervene, but in natural immunity against micro-organisms positive chemiotaxis is exhibited by the microphages more than the macrophages. He states that the sensitiveness of the two chief categories of phagocytes often exhibits a marked difference and that spirilla, for example, are ingested and destroyed exclusively by the macrophages of the guinea-pig which alone exhibit the necessary positive chemiotaxis. In many other examples of natural immunity the part played by the macrophages is masked by that of the microphages.

My own experiments were carried out with the peritoneal exudate of guinea-pigs following aleuronat injections. This exudate was mixed with equal quantities of .85 per cent. sodium chlorid solution and then added to the various bacterial suspensions in equal proportions in capillary tubes. These tubes were incubated at from 34 to 36° C. for thirty minutes when smears were prepared and the number of bacteria taken up by 20 microphages and by 10 macrophages estimated. For each test on such a peritoneal exudate fresh bacterial suspensions were prepared which contained as nearly as possible equal numbers of bacteria, but no attempt was made to have an equal number of bacteria for the several tests, so that the suspensions used for the different exudates did not contain equal numbers of bacteria.

A series of ten observations was carried out on the exudate obtained from ten different animals by employing the following cultures: *Bacterium pseudodiph-*

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

theriticum; two cultures of *Streptococcus pyogenes*, one from urine and from the throat of a case of scarlet fever; *Micrococcus catarrhalis; Micrococcus pyogenes albus* and *Micrococcus aureus*. The results obtained in these ten observations are shown in Tables 1 and 2, Table 1 showing the average number of bacteria taken up by the microphages, Table 2 showing the average number of bacteria taken up by the macrophages. While there is considerable variation in the results obtained with the different exudates it will be seen that in a fairly constant degree the macrophages had taken up a greater number of bacteria than had the microphages. This fact is shown more definitely in the means of the ten observations in the last column of each table.

Mic. catarrhalis.	2.9	1.1	0.6	3.0	1.9	18.7	4.4	6.5	2.0	4.0	4.51

A second series of five experiments was undertaken with the view of ascertaining the range of bacteria susceptible to phagocytosis under similar conditions. For these observations the following organisms were employed: *Micrococcus aureus; Microspira schuylkilliensis;* and *Bacillus dysenteriæ*, Shiga. The results obtained in this series of observations are shown in Tables 3 and 4. These results are too few in number and too erratic to warrant the formulation of any definite deductions. In several instances no phagocytic action could be demonstrated, and doubt existed usually whether the spirilla and dysentery bacilli were really within the phagocytes or were merely lying on them, or adherent to their exterior. The results indicate that the opsonic power of the blood serum is much more pronounced for those bacteria which induce septicemia than for those in which a more distinct bactericidal immunity is induced.

Paralysis of Ocular Muscles After Lumbar Anesthesia.—Loeser of Berlin publishes in *Med. Klinik* for March 11 reports of 3 cases of paralysis of the ocular muscles observed after spinal analgesia. The first patient was a man of 45, operated on for hydrocele. The evening after the operation, while healing was progressing smoothly, intense headache developed and vomiting. The headache continued, and when the patient got up for the first time on the fifth day, he presented symptoms of trochlear paralysis on the right side. Recovery was complete in a week or so. The second and third patients had been operated on for hemorrhoids or hernia under stovain; spinal analgesia, and abducent paralysis developed in direct connection with the operation. This paralysis subsided very slowly. In all the cases the first symptoms were noticed as the patient first left his bed.

Clinical Notes

THE TREATMENT OF FRACTURES OF THE FEMUR

WITH A DOUBLE ANGULAR PLASTER-OF-PARIS SPLINT AND ITS APPLICATION BY A SECTIONAL METHOD.

J. H. DOWNEY, M.D.
GAINESVILLE, GA.

Owing to the difficulty of obtaining the results without deformity and the great suffering and long confinement of patients suffering from fractures of the femur, this condition has interested the profession from time immemorial.

The different methods, devices and apparatus devised for the treatment of these fractures are too numerous to mention, and I have not added another wholly new one to this list, but have tried to get the best points of each and to combine them into one which will meet every indication of any fracture of the femur, whether of the neck, upper, middle or lower third, and one open to the fewest rational objections. It is conceded that no straight splint can be employed successfully in fractures of the upper and lower end of the femur. If this be true, then the straight plaster cast, Buck's extension and the long-side splint of Hamilton must be laid aside or used only in fractures of the middle third. The recognition of this fact led Esmarch to use a double inclined plane, Nathan R. Smith to devise his long anterior splint and, later, Hodgen his posterior suspension. These three last methods had the important idea in view of making the long fragment conform in direction to the short one, and at the same time to get the nearest approach to a natural restful position of the leg and greatest amount of normal muscular relaxation. Each of these methods meets the indications mentioned, provided the patient can be kept still, yet none of them meets the fundamental indication for which they were devised. "The objects in the treatment are to reduce the fracture, to maintain reduction immobilized until union is firm, and to restore the leg to its normal usefulness."

Does any method given in our text-books to-day meet the above-mentioned objects in treatment? I believe nearly all will agree with me that they do not, and most of them seem to have things reversed, as, e. g., the immobilization of the patient instead of the fracture. Each splint or device I have spoken of has many merits, especially the Hodgen, and I do not speak of them in a spirit of criticism, by any means. They have each served the profession well and have aided in relieving suffering humanity. As we can never reach a state of perfection, we must always be looking for something better. Let us combine the good points of all these methods and see if we can not meet all these requirements and at the same time give the patient a reasonable degree of comfort and safety and the freedom of any desired movement during this long process of repair without increase in present pain or risk of future deformity. Esmarch, Smith, Hodgen and Cabot's apparatus give us position; Buck's apparatus, extension; plaster-of-Paris, fixation.

AUTHOR'S DEVICE.

I want to combine all these important points in one universal dressing known as the double angular plaster-of-Paris splint, which, if properly applied, will meet every indication.

To illustrate, let us assume that we have a supercondyloid fracture. We must flex the leg on the thigh, the thigh on the abdomen. then apply a plaster-of-Paris cast from the base of the toes to just above the knee in this properly flexed position (Fig.1); make the cast a little thicker just below the knee and allow the plaster to set: when sufficiently hard, which takes about ten minutes, arrange for extension and counter-extension.

If not provided with an apparatus like than shown in the illustrations, a folded sheet may be passed between the legs and brought well up against the perineum with a strong man holding each end. Have another assistant place the right hand under the knee, the left hand over the front of the lower end of the tibia. By these assistants pulling in opposite directions the necessary amount of extension can be effectually made in this position and all the aid of natural muscular relaxation possible obtained.

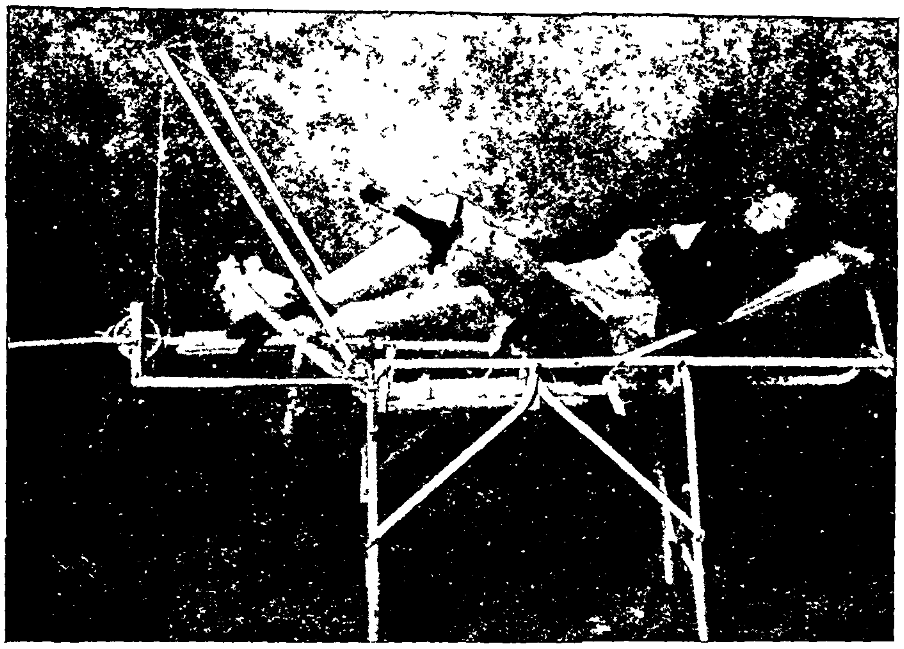

Figure 1.

The traction being steadily kept up. the fragments are brought into apposition and held firm while the upper section is applied. Pad the parts to be covered by plaster in cotton batting held by a roller bandage; take a couple of heaping tablespoonfuls of dry plaster, moisten to the consistency of thin dough. rub thoroughly around the upper end of the lower section, start with the plaster roller at this point and go up in the usual way to the ensiform cartilage, making as many layers as necessary to give the desired strength. Opposite the hip joint there is only a three-fourths circle in the cast: this makes a weak point and is one of the greatest strain. consequently reinforcement will have to be made thoroughly or it will break. This can be done by an up-and-down back-and-forth application of the plaster roller or by placing between the layers of plaster narrow strips of tin or strips of fine wire gauze. The addition of a few extra turns of roller at the welding point just above the knee completes the dressing (Fig. 2)

ADVANTAGES OF THE DRESSING.

Note carefully the position of the limb in Figure 2. There are two angles. one at the knee. the other at the hip. These angles serve a threefold purpose:

1. *Position.*—By placing the muscles in a natural state of relaxation the long and the short fragments are accommodated and brought in line with each other. They serve as points of fixation, prevent shortening and laxation which is a great comfort to the patient. It places him in a fixed sitting position, which can be assumed at will in comfort. In walking with the crutch the foot is out of the way; when in bed he can lie on the side or back by placing a folded quilt under the knee. By this splint we give the patient the freedom of every movement without fear of pain or injury.

2. *Extension.*—We could ask no better extension than that afforded by the abrupt angles at the knee and hip.

3. *Fixation.*—The plaster cast is the most perfect form of fixation, fitting the limb as accurately as an elastic stocking; it prevents movement of the fragments, muscular contraction and pain.

By this method three-fourths of the horrors of fracture of the femur are done away with by giving the patient the freedom of lying, sitting or walking at his pleasure with the assurance of a good result, and all this with a remarkably small amount of pain. Can as much be said for any other method? What objection or drawback is there to this method? There are two: One is the weight of cast sufficiently strong to be effectual; the other is the danger of swelling of the limb and the cutting off of the circulation to the distal portions. As to the first, a plaster cast on an adult six feet high and weighing 175 pounds. from base of toes to ensiform cartilage on the second day, after evaporation has taken place, weighs approximately eight and one-half pounds; an extra heavy one would weigh ten pounds. This is nothing when compared with a ten- or fifteen pound Buck's extension weight or partial body suspension by a Smith or Hodgen's splint.

The greatest drawback or danger is swelling or obstruction of the circulation. This can be obviated by laying the cast open and applying an ordinary roller bandage; with this there is no more danger than from any other splint. and yet it fits the limb perfectly, and later. when swelling subsides. a strip can be cut and the edges brought together, and there is still a perfect splint. one that will give comfort and pleasure to the patient. success and happiness to the physician.

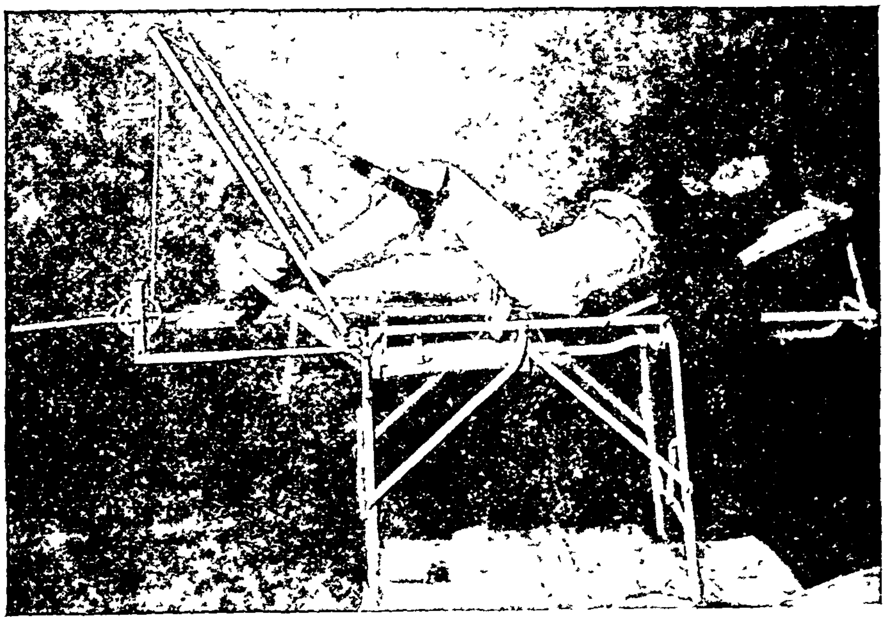

Figure 2.

A CASE OF TOTAL ATROPHY OF THE STOMACH.

G. PAUL LAROQUE, M.D.
AND
MATT O. BURKE, M.D.
RICHMOND, VA.

The following case is worthy of record. The condition is exceedingly rare and should not be confounded with hysteric affections on the one hand nor with gastric carcinoma on the other. The patient was studied by us through the courtesy of Dr. Stuart McGuire.

History.—Two years ago, a dentist, about 35 years of age, after a couple of years very hard work associated with much loss of sleep, suddenly became the victim of "nervous breakdown," and at about the same time after dietetic indiscretion, suffered acute gastritis. From the latter he rapidly recovered and was advised to take a sea voyage, which he did. The voyage was rough and he was made violently seasick for a week. After this he began to take excessive care of himself and particularly of his stomach, carefully avoiding eating a full meal and never completely gratifying his hunger for fear of an attack of indigestion. On questioning him carefully we learned that he had not had indigestion since his primary attack and that since he was seasick he had not vomited nor been nauseated.

Symptoms.—His symptoms throughout were negative save that he had emaciated in the past 18 months from his normal weight of 160 pounds to 80 pounds. He had had at no time any colic or indigestion or pain either before or after eating. He had lost correspondingly of strength and his bowels did not move as regularly as they previously did, still he was not constipated. He had been regularly hungry till the last 6 months but was always afraid to eat. For the past 6 months he was less hungry than formerly. Since the beginning of his illness he had not taken at any time a full meal and during the past 6 months had lived on fluids with an occasional piece of toast. The greatest quantity, even of milk, which he had taken, was two-thirds of an ordinary tumblerful, and now even this caused fulness in the epigastrium.

Physical Examination.—Patient was a remarkably emaciated man in whom every superficially-placed bone can be outlined. He was slightly anemic and yet his appearance was not that of cachexia. Weight, 80 pounds. His tongue was clean, red, small and moist. Exhaustive examination of every organ in his body failed to detect evidence of disease, except in the stomach. The abdomen was scaphoid in shape, so much retracted that the pulsations of the abdominal aorta were distinctly visible. There was no rigidity nor tenderness anywhere and the anterior portion of the spinal column was easily palpable through the abdomen. The pylorus could not be felt. Urine and feces were perfectly normal.

A test meal of bread and water was administered and could not be recovered at the end of an hour. The effort to wash his stomach was so exhausting to him that this was not attempted again till he could be strengthened by stimulating nutritive enemata. At the end of about a week after a test meal, the gastric contents showed an entire absence of HCl and yet no lactic acid was found. His gastric capacity was greatly diminished (stomach held only 8 fluid ounces).

Diagnosis.—Voluntary starvation. Secondary atrophy of the stomach.

Treatment.—He was placed under nourishing treatment. His dietary was carefully arranged so as to avoid at any time giving him sufficient quantity to cause the slightest discomfort, lest he should again become afraid to eat. He was, therefore, fed small quantities often, gradually increasing the quantity and increasing the intervals between feedings, in a manner very similar to that employed in training an infant stomach to solid food

Under this treatment the patient gained 5 pounds weekly for 5 weeks. By this time he was on regular house diet but since he could not take a full meal at once, he was given eggs and milk between meals. About this time he failed to gain more than about a pound a week. A week or so later his gastric contents still failed to show HCl.

Operation.—The man being about 35 years old, it was decided to make an exploratory incision in the hope that carcinoma of the stomach could be discovered in time for radical cure. Operation revealed an atrophied stomach about the size of an ordinary tumbler with no sign of infiltration nor any evidence of structural change.

A CASE OF TETANUS NEONATORUM WITH RECOVERY.

E. L. DEWEY, M.D. AND W. E. PUTNAM, M.D.
WHITING, IND.

History.—Infant. F., aged 10 days. Mother and child attended by a midwife until the ninth day, when the pre illness began. The mother noticed that the baby was cross irritable and was unable to nurse, and the jaw was set.

Examination.—Temperature, 101.5. Trismus, rigidity an traction of the neck were marked. The navel was red swollen, and several drops of pus were pressed out.

Treatment.—The infected area was opened with a knife cauterized with 95 per cent. carbolic acid. Ten cubic c meters of antitetanic serum were administered over the se nerve at the gluteal fold. Two grains of chloral hydrate four grains of potassium bromid were given by rectum e four hours. Camphorated tincture of opium was given in drop doses as often as necessary to keep the baby sleeping. child was nourished with mother's milk given with a med dropper, the jaws being separated with the finger for the pur

Course of the Disease.—July 18: At 8 a. m. the tempera was 100.4; at 2 p. m. it was the same. Ten cubic centim of antitetanic serum were administered over the sciatic at the gluteal fold. The opium, chloral and bromid were tinued. The rigidity extended to the muscles of the back lower extremities: their were opisthotonos and cynosis i baby was disturbed.

July 19: At 8 a. m. the temperature was 102.4; at 2 it was 103.6. Antitetanic serum was again administered i same situation. At 8 p. m. the temperature was 101.3. bromid and opium were continued. The opisthotonos and osis remained about the same.

July 20: At 8 a. m. the temperature was 103.2. Ten centimeters of antitetanic serum were injected into spinal between the fourth and fifth lumbar vertebræ. At 7:30 p. temperature was 100.6. The same amount of antitetanic was injected into the spinal cord at the lumbrosacral joint minims of a 5 per cent. solution of carbolic acid were hypodermatically every three hours and increased 5 mini each dose till 20 minims were being given at each dose. chloral, bromid and opium were continued. The trismu less marked; the opisthotonos and cyanosis were still pr The child was able to take nourishment from the nursing

July 27: Chloral and bromid were discontinued an centimeters of antitetanic serum were injected into the cord between the third and fourth lumbar vertebræ. At 8 the temperature was 98.6. There was some trismus and ri of the back and lower extremities when the baby was dist

July 22: At 8 a. m. the temperature was 98.6; at 7 p. was 101.2. Ten cubic centimeters of antitetanic serum injected into the spinal cord between the fourth and fifth vertebræ. The chloral, bromid, opium and carbolic acid continued.

July 23: At 11 a. m. the temperature was 98.6: at 8 it was 99.2. The hypodermic injections of carbolic acid discontinued.

July 24: At 8 a. m. the temperature was 98; at 8 p. was 98.6. There was still some rigidity of the back and extremities when the baby was disturbed.

July 25: At 8 a. m. the temperature was 98.6; at 8 it was 98.8. The chloral and bromid were ordered given times a day.

July 26: At 8 a. m. the temperature was 98.4. The was able to nurse from mother for the first time since t ness began. There was a diffused erythema all over the There was no rigidity of the back and lower extremities.

July 26: Chloral and bromid were discontinued an child was discharged cured on July 29.

THE JOURNAL OF THE

[For other information see second page following reading matter.]
SATURDAY, AUGUST 25, 1906.

The space given to statistics of colleges and state boards in this issue, our annual Educational Number, requires the omission of some departments and the abbreviation of others.

As will be noticed, we have combined in this number the statistics relating to the examinations for license to practice medicine conducted by the various state licensing and examining boards during 1905, with the medical college statistics covering the year ending June 30, 1906. While there are advantages in combining all this matter in one issue of THE JOURNAL, we find it not altogether satisfactory. In the first place, the statistics regarding the state board examinations might have been published at least three months earlier. Again the work connected with tabulating this matter, making deductions, etc., is very great, and this makes the labor burdensome when it all comes at the same time. We shall probably hereafter, therefore, publish the statistics in two different numbers, as we have done in the past.

COUNTRY PRACTICE.

Suggestions as to available locations for physicians can scarcely be out of place at any time, but we are inclined to believe that, owing to hospital appointments. postgraduate vacations and discouragement after ineffectual attempts to secure a foothold in crowded centers, during the "healthiest" season of the year, a very large proportion of the members of spring graduating classes are seeking locations late in the summer and early in the fall.

In England, there is an ethical and economic rule, not, of course, strictly enforced, that the young physician shall seek an actual vacancy, left by the death or retirement of a practitioner. In this country, no such principle is recognized and competition. provided that it is fair and honorable, is allowable. With considerable justice. the young graduate is often advised to select the most desirable location that he can possibly command, even at some risk of failure, to make his charges equal to those of the most firmly established practitioners of the neighborhood, to hang out his sign in the same row with the most successful older men and, in general, to aim high.

With all deference to the idea that every barefoot boy may be president and that neither heredity nor early mental mediocrity is a bar to success, there is much wisdom in having the young man in any profession, indeed, before selecting his life work, make a careful, impersonal, judicial canvass of his probable capabilities, and such a course would undoubtedly result in less aggregate waste of effort, less humiliating disappointment and greater total achievement than the policy of following the dreams of ambition. "Aim high" is a specious motto. "Aim to hit the mark," with regard to the carrying power of the weapon and ammunition possessed, is a much better one.

It is obvious that one who has a reasonable ambition for medical teaching, hospital work and specialization should remain in a city, though not necessarily the one in which his medical studies have been pursued, nor should longitude be too slavishly considered. For the man whose tastes and aptitude mark him for the general practice of medicine, the country or small town should receive fair consideration and the prejudice in favor of the city should be taken only at its true value.

A practical, initial reason for preferring the country—and we shall include in this term the village or small town in which most so-called country doctors actually reside—is that the English rule of seeking a real vacancy can be followed more literally than in the city. Any possible fluctuation in the medical population of a large city fails to create a genuine need of another practitioner or to render it impossible for one or more to secure a foothold without displacing some one else. In a village with its tributary country, it is, on the other hand, easy to determine whether a vacancy exists or not. The fact should not be overlooked that to attempt to establish oneself in such a community by driving out a veteran physician may and should fail.

It may be stated as a fact, that, in this country, less than 600 inhabitants support one physician. Unfortunately, this support is far from ideal and the ratio should be very much larger. Obviously, the general wealth of a community, its dependence on medical charity, and the prevalence of disease, accident, and the birth rate, must be considered, as well as the arithmetical ratio. It is also a matter of general observation that a new—not necessarily a young or even a recently graduated physician—in a city, requires about three years to build up his practice to a point at which he can be self-supporting, unless he has unusual influence or unless the circumstances are otherwise unusual. In the country, a practice may reasonably be expected to be adequate for self-support within a year and the same statement applies to certain isolated—but not often desirable—sections of cities. Salaried positions, on a fair living basis and in ethical lines of medical work, afford support for about 2 per cent. of the medical profession, but the more desirable, as in the government medical service, state institutions, private sanitariums and municipal boards of health, are not available for the average man or for immediate selection after graduation.

The urban population of the United States—meaning residents in towns and cities of 8,000 and over was 20.9 per cent. in 1870, 22.6 per cent. in 1880, 29.2 per cent. in 1890 and 33.1 per cent. in 1900. It is obvious that a town of 8,000 inhabitants is not a city in the ordinary social and sanitary sense and that physicians residing in such towns must have a considerable amount of country practice. These statistics show that there has been, in the last ten years, a decided slowing of the tide from country to city, especially if we consider that the natural, local increase of population in cities is a large factor in the total increase for the nation and that the same growth would bring a great many villages past the 8,000 limit. At any rate, from purely statistical reasons, it is obvious that two-thirds of the recent graduates should seek locations in the country, and probably this fraction would be increased to four-fifths if we include as cities, only such centers of population as have 15,000 or more inhabitants.

As a matter of fact, an approximate study of statistics shows that the normal distribution of physicians is not maintained. For example, the cities of New York state, of 100,000 or more inhabitants, containing about 52 per cent. of the population, have about 70 per cent. of the physicians. While the support of many specialists and physicians of note, living in cities, receives a substantial contribution from the country, this applies to relatively few in the aggregate and seldom amounts to more than a quarter of the total income of an individual physician. Moreover, large cities contain, to a disproportionate degree, persons who can not help in the support of our profession.

Passing from the statistic to the general impressionistic argument, we find that the young physician supported outside his practice is a type almost solely limited to cities and that while the gross income of a fairly mature and successful physician in a small village or town usually averages from $2,500 to $5,000, probably not more than 20 per cent., if as many, of city physicians, pass the lower figure. A strictly country practice, however, rarely exceeds $3,500, the fees and distances covered in visiting patients rendering it almost impossible to do a larger "business." On the other hand, it should be remembered that the scale of living and the actual prices of rent or its equivalent, maintenance of equipage, provisions, etc., are much lower in the country than in the city. Thus, as compared with his clientele or with his professional colleagues, the country practitioner with a gross income of $1,500, is as well off as the city practitioner with a gross income of $2,500.

It may not be out of place, also, to point out that the country or small village by no means corresponds at present to the description of rural simplicity of the fifth reader and that the twentieth century country doctor in most parts of the United States, is much less of a hero and more fortunate in his material and social life than Ian MacLaren and various other writers of fiction would give us to believe.

The city dweller is too apt to imagine that what have been called city conveniences are out of the question in the country. Water supplies, gas and electricity are becoming common in villages of even 1,500 inhabitants and less. Even where coöperation has not already secured these conveniences, the improved wind mill or gasoline engine and acetylene or naphtha gas plants, place them within the reach of any fairly well-to-do country resident at an initial cost which is not excessive, when the cheapness of maintenance is considered. The telephone is also, now, relatively as common in the country as in the city and is much less expensive. Rural free delivery of mail and local deliveries of merchandise are also in common use.

It is true that educational and social advantages are easier of access in the city, yet good high schools, in the more enlightened states, are found in practically every village, local libraries are common and many public libraries in cities have arranged for suburban service. In many parts of the country, the train or trolley service to and from large cities places the resident of a village thirty miles away within easy and rapid access of the business center.

Of course the ambitions of the country doctor are somewhat limited in regard to certain forms of professional activity. At the same time, these limitations are by no means so serious nor so absolute as might appear. The tendency is for medical teaching to become more and more a specialty by itself, conducted for the most part by men who do not engage in practice. Conversely, the physician, as such, is tending to return to the status of a private practitioner and to make his reputation accordingly. Small hospitals have arisen in the small towns and a great deal of good surgery is now done in communities tributary to large cities which was formerly done by the city surgeon.

It must be admitted that the rural districts described in the pioneer tales and in the fifth reader still exist and that the simple life there found is not particularly attractive to the average twentieth century American. On the other hand, forces are at work with an ever increasing momentum to check the excessive development of urban life at the expense of rural life and to render the country and small village more and more desirable, not only for our own profession, but for the better class of the population generally. The man who somewhat anticipates the turn of the tide of population may well feel that he is making a wise investment for the future.

THE NECESSITY FOR BETTER PROVISION FOR LEGAL MEDICINE IN THIS COUNTRY.

Medical jurisprudence or legal medicine, considered as a distinct discipline, is fast becoming a neglected subject in the American medical curriculum. It is true that many state boards specify a certain amount of instruction in something that is loosely called medical jurisprudence, but it does not appear that the exact field of knowledge that this subject should cover has been accurately defined and, judging from the lists of questions published from time to time by state boards, little or no attention is paid to the subject in the various state examinations for license.

It is also true that many of our medical schools offer brief courses of instruction in medical jurisprudence, but such a thing as a definitely organized department of medical jurisprudence with the necessary laboratory and other special facilities does not appear to exist in any of our medical schools. The actual state of affairs in this respect may be learned from the following summary of the work actually given in some of our well-known medical schools:

1. Harvard Medical School has a voluntary course of six lectures by a local judge. The course is not taught as a separate study, instruction being given by the various departments in the medicolegal aspects of the various subjects.
2. Johns Hopkins University. Instruction is given in the third and fourth years, definite number of hours not given, excepting one hour a week; probably between twenty to thirty hours given.
3. University of Michigan. Thirty hours of lectures given to the joint senior classes in law and medicine.
4. Northwestern University Medical School gives eight lectures and sixteen recitations in senior year.
5. Yale Medical School, during the senior year, gives one hour a week for two terms, total about twenty hours, which is devoted entirely to lecture work.
6. University of California, during the third year, gives about twenty hours of lecture work.
7. University of Minnesota, during the last half of the senior year, devotes between sixteen to twenty hours to lectures and recitations.
8. Washington University, St. Louis. During the second part of the senior year, between twenty-five and thirty hours are given to lectures by different men, including two lectures at special postmortem.
9. University of Pennsylvania, during the first part of the fourth year, devotes about sixteen hours to the subject.
10. McGill University, Montreal, devotes twenty hours during junior year to lectures and practical work. The practical work takes up blood stains both with the microscope and spectroscope.

The New York schools, Columbia, Bellevue, and Cornell, make no mention of the subject whatever. Medical jurisprudence is not among the courses required by the New York Board of Regents.

In our large cities the appointment of untrained men, which so far has been the rule, to such places as coroner's physician, as well as the frequent changes for purely political reasons of such appointees, coupled with loose administration and total failure to provide permanent and proper facilities for even only the routine work, have long since accustomed us to put up with much that is crude and discreditable in this important branch of public service. At the same time as this is true in general, it should not be forgotten that we have many men who, by devoting themselves to special lines, largely in the capacity of private experts, have become recognized authorities in their chosen fields of legal medicine. In the smaller towns and the rural communities, in which the opportunities for medicolegal work necessarily are limited, the appreciation of some of the most fundamental medicolegal principles must often be slight if one may judge, for instance, from the number of improperly conducted and incomplete postmortem examinations in suspected criminal cases. The fundamental rule that in order to establish definitely the real cause of death (whenever that is possible) it is essential to examine all the body is frequently neglected and sometimes this neglect results in the miscarriage of justice.

In other countries legal medicine appears to receive a far greater degree of attention than in ours. As examples may be cited Germany and Austria, with their professorships of legal medicine, their special medicolegal institutes equipped with the necessary laboratories and apparatus for pathologic and chemical work; here also a certain amount of definite knowledge of the subject on the part of the applicants is necessary for license to practice medicine. In France and Italy this subject receives also special attention, and the late Professor Brouardel, of Paris, was one of the great authorities in this field. In Europe special journals have existed for years devoted to the publication of scientific investigations, practical observations and discussions of medicolegal problems. When one considers the relative paucity of original contributions to medicolegal subjects here, the impression results that conditions in this country so far surely have not been so favorable as one would wish for the growth of interest in and appreciation of the practical and scientific importance of this special branch of medicine.

The remedy? Improvement in the existing conditions which are unsatisfactory from the point of view of the public and discreditable to the medical profession, must be sought in at least two different directions. In the first place, provision should be made for the appointment in our larger cities, where the normal amount of criminal and other medicolegal work clearly warrants it, of medicolegal experts, especially in pathologic and chemical lines. These appointments should be permanent and they should be made according to merit, and not, as at present, for political reasons, when made at all. The salaries should be large enough to attract good men to the positions. When we consider the character of the work and the special qualifications necessary to do it well, the hardships of such positions should command at least about the same grade of salaries as are paid to those professors in our better university medical schools who devote themselves wholly to the teaching of and investigation in the fundamental branches. Then there should be provided assistants and adequate facilities for the work in the form of suitable postmortem rooms, with laboratories and apparatus for microscopic, bacteriologic and chemical purposes and with space for the establishment of museums in which valuable specimens of various kinds could be placed for use in instruction and study. In many of our cities an arrangement of this general character would be economical, because the large special expert fees now paid in so many notorious murder cases would be rendered largely unnecessary, to say nothing of the greater promptness and thoroughness of the examinations.

On account of the relatively small population of our ordinary counties (exclusive, of course, of those containing large cities), it can not be expected that each county ever will maintain a permanent, competent medicolegal expert. On the other hand, the state might well establish a state medicolegal office or institute for the purpose of furnishing (outside of the larger cities) prompt and skilled medicolegal service in criminal and other cases demanding such service.

In the second place the instruction in legal medicine in the medical schools should be improved and extended. By this it is not meant that a full, new department, with separate staff and equipment, must be established in every medical school in the country. This would be possible, to a greater or less degree, in the case of only a small number of university schools that could enter into mutually advantageous relations with the city in which they are located (or possibly with the state). Thus, the professor of legal medicine in Harvard University, for instance, might very well be the chief medicolegal officer of Boston—indeed, we believe some arrangement like that now exists—the institute and equipment being furnished in accord with arrangement between the city and the university. Naturally, the students in schools so favorably situated as this would be in this case would enjoy special advantages, and in time these advantages would be sought by those who desired to become specially trained in medicolegal work. In other words, schools of this kind would become special centers for the training of men in what we are calling legal medicine. And such centers may be needed more and more in the future as the opportunities for careers in legal medicine increase and enlarge.

In the medical schools in general in which legal medicine can be taught only in outline or in which instruction is supposed to be given by the various departments in the medicolegal aspects of their various subjects, it would seem to be desirable that the faculties make special efforts to strengthen the work, and especially in the direction of better co-ordination between the various departments. Thus, it is particularly necessary that students be instructed more carefully in the matter of postmortem examination in medicolegal cases. Experience in criminal cases, especially in cases of abortion and poisoning, shows that practitioners often have no adequate conception of the thoroughness and objectiveness required.

If it were possible to promote development in the directions outlined, there would soon be established in this country higher standards for medicolegal work, at least in the lines touched on here, and the law in general would receive more direct and greater benefit now of existing technical knowledge in medicine.

EXAMINATION FOR A HIGHER MEDICAL CERTIFICATE IN FRANCE.

An interesting and important decree has recently been promulgated by the Minister of Public Instruction of France, which appears in the *Semaine Médicale*, August 1, under the heading, *"Décret instituant un certificat d'études médicales supérieures,"* and which is commented on at some length in the same issue by Prof. Ch. Bouchard.

The degree outlines in detail a new plan of examination for those who desire to secure a certificate of superior attainment which will make them eligible to positions in any of the medical faculties of France, or which may serve as evidence of especial qualifications wherever they may wish to pursue research or engage in teaching. The statute of 1874 required that a candidate for a teaching position must hold himself in readiness to pass an examination at any time in any or all of the branches of medicine. The obligation thus imposed on the young physician to keep fresh in memory an enormous mass of facts entailed such an expenditure of time and energy that it operated as a serious bar to original investigation. To this Professor Bouchard attributes the fact that France was relatively sterile in research and original contributions to knowledge until 1887, when the law was modified by eliminating the examinations in anatomy and physiology, and by permitting the candidate in immediate preparation for the oral test in pathologic anatomy to have access to books in the national library. He was also required to submit a thesis embodying the results of his own researches. Unhappily, however, this resulted in neglect of the young physicians to keep up their interest and their knowledge in the medical branches, other than those in which they were engaged in research, and the result, while greatly stimulating investigation in special lines, the fruits of which have been abundant and gratifying, was the production of a body of younger men not possessing that broad general information which is indispensable to the successful teacher.

The recent degree may be regarded as a compromise between the statute of 1874 and the amendment of 1887. It provides for examinations, to be held semi-annually, by properly constituted juries, in twenty different groups of subjects, and the examination is to consist of: 1. A composition on anatomy, physiology and histology, lasting four hours, the question discussed to be one of three drawn by lot from those provided by the jury. This examination is to be held in a closed room, without access by the candidate to any aids whatsoever. 2. An oral examination on one of three question in general pathology, similarly drawn, to continue not more than three-quarters of an hour after three hours for preparation by the candidate in a closed room without aid; and, 3. A practical demonstration in pathologic anatomy, comprising the various methods of exploration of the tissues and organs.

Similar examinations are provided for candidates who seek positions in the schools of pharmacy. The first examination is to be held in October, 1907, and, after January, 1908, they are to be held semi-annually. Each jury is to be composed of nine members, selected by the Minister of Public Instruction from the faculties of France, not more than four members of any one school, however, to be drawn on any jury. The candidate may submit to one, two or all three of the tests at any one examination as he may elect. Having satisfactorily passed these examinations, he is to receive the *"certificat d'études médicales supérieures,"* and he will not thereafter be required to take any further examination, but becomes at once eligible for appointment in any faculty of his choice, when there may be a vacancy, as chief of clinic, laboratory assistant or substitute professor.

It is apparent that the new plan has been considered with great care by the council for higher education of France, and is expected to result in a decided improvement in the quality of the accessions to the medical faculties, while, at the same time, it will preserve to the younger physicians that leisure, freedom and tranquillity of spirit which are essential to original investigation.

AN INCREASE IN MEDICAL COLLEGES.

One discouraging thing in the statistics published this week is the fact that, while small, there has been an increase rather than a decrease in the number of medical schools. On the other hand there is, here and there, an indication of a desire for betterment by combining institutions. During the year the Central Medical College of St. Joseph, Mo., and the Ensworth Medical College of St. Joseph, Mo., merged into the Ensworth-Central Medical College of St. Joseph, Mo. The Medico-Chirurgical College of Kansas City, Mo., the Kansas City Medical College of Kansas City, Mo., and the College of Physicians and Surgeons of Kansas City, Kan., united to form the Medical Department of the University of Kansas. The most noteworthy merger, however, was that through which the Fort Wayne College of Medicine, the Medical College of Indiana and the Central College of Physicians and Surgeons of Indianapolis became the Indiana Medical College, the school of medicine of Purdue University, the latter a semi-state institution. Each of these three schools had become a well-established and recognized institution, and considerable self-sacrificing spirit was shown on the part of the members of each of the faculties in giving up their respective institutions for the sake of having one good school in the state. It is to be regretted, therefore, that another school is being started in Indianapolis, so that, in spite of the merger, there are still to be two schools in that city. We make this comment as a general proposition without entering into the merits of the case. It is, however, such instances as this that discourage those who are desirous of eliminating weak schools by combining two or more into one strong one. In several locations where two, three or more colleges are struggling along with difficulty, not able to do good, efficient work through lack of equipment, futile efforts have been or are being made to unite them into one institution. Doubtless in time personal ambition on the part of the few will give way to the best interests of the many and minor difficulties be overcome and one strong college take the place of two or more weak ones. Standing, as our country does, as one of the leading nations in commerce, in the arts, in the sciences and in general education and enlightenment, it is certainly to be deplored that she remains a laggard in standards of medical education.

COLORADO'S NEW REQUIREMENT.

The Colorado Board of Medical Examiners has adopted new requirements regulating medical licensure which are certainly to be commended and which place that state far in advance of its former position. Up to the adoption of this new schedule, Colorado was among the states which did not require an examination of all applicants and which registered non-graduates. Graduates of the Colorado schools will hereafter be required to take the examinations the same as graduates of schools outside the state. Provision has been made for old practitioners by special sections, exempting them from the more exacting requirements that apply to recent graduates. The new schedule also contains a provision whereby commissioned medical officers of the United States Army, United States Navy and of the United States Public Health and Marine-Hospital Service may be registered without examination. This offers one class of credentials which it seems to us might be accepted in other states.

CALIFORNIA STATE SOCIETY JOURNAL OUT OF THE ASHES.

The California State Journal of Medicine, Phoenix-like, has risen from the ashes of the earthquake and fire. The June number appears in the old form and size, and Editor Jones is giving evidence that he is in business at the old stand. In the number before us, however, there are items that indicate that things are not as they were. "Please do not ask for back numbers of the *Journal,* for there are none," we read. "Please don't ask for copies of the constitution and by-laws, or for back numbers of the Register of Physicians, or for programs, for there are none." The state society seems to have been in unusual ill luck, for, while practically everything was wiped out by the earthquake and fire, another visitation was made on the night of July 21, when a new edition of the register, i. e., the state directory of physicians, was destroyed by fire at Mountain View, where the printing and binding were being done. We extend our sympathy to the state society officers, but congratulate them on the energy they are displaying. The offices of the society are now located at 2210 Jackson street, San Francisco.

MEDICAL EDUCATION IN THE UNITED STATES.

In this number appear statistics regarding medical education in the United States for the year ending June 30, 1906. The information was obtained direct from the colleges, from the annual announcements and from other sources, special care being taken to insure correctness in every instance. We desire to express our appreciation of the assistance rendered by the officers of the medical colleges.

While there is much to regret regarding medical education in the United States, there is much to encourage the belief and hope that improvement is being made. Many of the colleges are, of their own volition, raising their standards, either by increased entrance requirements, by longer sessions, by offering better courses or by all of these. Many of the state licensing boards are also demanding higher entrance and graduating requirements, and are continually urging and adopting changes for the better. The various college associations are wielding a good influence. The establishing of a Council on Medical Education is having a decided effect. State medical societies are establishing permanent committees on medical education, some of which have already done energetic work. The outlook, we repeat, is encouraging.

Number of Medical Students.—The total number of medical students (matriculants) in the United States for the year ending June 30, 1906, was 25,204, a decrease of 943 below last year. Of this number, 23,116 were in attendance at the regular schools, 1,085 at the homeopathic, 644 at the eclectic, 110 at the physio-medical and 249 at the nondescript (unclassifiable) schools. The attendance at the regular schools shows a decrease of 1,003 below that of last year, a decrease of 546 below 1904 and a decrease of 1,814 below 1903. The number this year is the smallest since 1900. In the homeopathic school there was a decrease of 19 below the attendance of 1905, a decrease of 224 below 1904, there being a constant decrease since 1900, and the attendance for each of the past two years has been below that of 1880. The eclectic schools show a slight increase over last year, although the figures of each of the last two years are smaller than previous years since 1900. The physio-medical colleges had 110 this year, against 114 last year and 129 in 1904.

Table 4.—Medical College Attendance.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880......	9,776	1,220	830	...	11,826
1890......	13,521	1,164	719	...	15,404
1900......	22,710	1,909	552	...	25,171
1901......	23,846	1,683	664	224	26,417
1902......	24,878	1,617	765	241	27,501
1903......	24,930	1,498	848	339	27,615
1904......	23,662	1,309	1,014	357	28,142
1905......	24,119	1,104	578	346	26,147
1906......	23,116	1,085	644	359	25,204

Graduates.—The total number of graduates for the year ending June 30, 1906, was 5,364, a decrease of 242 below 1905, 383 below 1904 and 334 below 1903. The number of graduates this year is the lowest since 1902, when it was 4,999. For the year just closed the percentage of graduates to matriculants was 21.3, or practically the same as for 1905. The percentage was 30.3 in 1904 and 22.8 in 1903. The number graduated from the regular schools was 4,841, or 285 less than in 1905 and the smallest number since 1902. From the homeopathic colleges 286 were graduates, showing an increase of 10 over last year. The eclectic colleges graduated 186, an increase of 33 over last year.

Table 5.—Medical College Graduates.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880......	9.776	380	188	...	3,241
1890......	3,853	380	221	...	4,454
1900......	4,715	413	86	...	5,214
1901......	4,879	387	148	...	5,444
1902......	4,498	336	138	27	4,999
1903......	5,088	420	149	41	5,698
1904......	5,190	371	146	40	5,747
1905......	5,126	276	153	51	5,606
1906......	4,841	286	186	51	5,364

Women in Medicine.—During the past year there were 840 women studying medicine, or 3.3 per cent of all medical students, as against 4.1 per cent last year. There were 233 graduates this year, or 4.5 per cent. of all graduates. In 1905 there were 1,073 students and 219 graduates, while in 1904 there were 1,129 students and 244 graduates. Of all women matriculants, 189 (22.5 per cent.) were in attendance at the three medical colleges for women, as compared with 221 (20.6 per cent.) in 1905. From these schools there were 33 (14.2 per cent.) graduated, as compared with 54 (24.5 per cent.) in 1905. The others matriculated in and graduated from co-educational colleges.

Number of Colleges.—During the past year eight colleges ceased to exist, seven (which are mentioned in another column) united with other colleges, and one, the Harvey Medical College, an evening school of Chicago, became extinct. Nine new schools have been organized. All these were regular colleges. The number of homeopathic, eclectic and physio-medical colleges remains the same. The total is 161, as against 160 last year. Of this number, 130 are regular, 18 homeopathic, 9 eclectic, 3 physio-medical and 1—the National Medical University of Chicago—is unclassifiable. Seven of the regular colleges listed do not grant degrees, teaching only the first and second years of the medical course. Sixty-one regular colleges are members of the Association of American Medical Colleges; 14 belong to the Southern Medical College Association; all the homeopathic colleges are recognized as in good standing by the college committee of the American Institute of Homeopathy, and all the eclectic colleges are members of the National Confederation of Eclectic Medical Colleges.

* Registers a considerable number of graduates of home colleges without examination. No reports from Georgia and Missouri.

physicians and, if the results of these examinations may be taken as a guide, the class of physicians. In the last two columns the rank of each state is given; in the first according to the number of applicants, and in the second according to the success of the graduates in passing the examinations.

Table F, also based on the first four tables, allows us to make comparisons among the larger colleges, or the 51 colleges having 50 or more candidates examined during the year 1905. There were 154 colleges in all which had candidates examined by state boards, of which 14 had 100 or more examined and 37 had between 50 and 100 examined. Therefore, 33 per cent. of the colleges had 50 or more candidates, while 103 (67 per cent.) had less than 50 each. There were 70 (45 per cent.) which had less than 25 candidates each. In other words, 2,350, or about 31 per cent. of all the candidates, came from 14, or 9 per cent., of all colleges, while 4,893, or 64 per cent., of all candidates came from 51, or 33 per cent., of the colleges.

In making comparisons, beside the percentage, one must consider also the number examined and the number of state boards before which the college was represented. The above group—Table F—is arranged according to the number examined. As to the representation before state boards: Jefferson leads, its graduates appearing in 35 states. Rush Medical College comes next, its graduates appearing in 30. Northwestern University Medical School and the University of Pennsylvania each had graduates appearing in 27 states. The College of Physicians and Surgeons, Chicago, the College of Physicians and Surgeons, New York, and the Baltimore Medical College each had representatives in 26 states.

Table G is based on the examination of graduates of 1900 to 1905, inclusive, i. e., *"recent graduates."* All graduates who were examined in the state in which the college is located are grouped in one column, while all the graduates of that college who were examined in other states are in another column. This is for the purpose of showing the number of graduates who stay in the state in which the college is located; also to show what is evidently a fact, that, as a rule, the graduates of a certain school have a much better chance of passing the examination in the state in which the school is located than they have elsewhere. This should always be con-

The ideal basis for reciprocity would of course be uniform—and therefore equally high—standards by all the boards. But this is considered by many an idea too utopian to be considered. As conditions now exist, states having comparatively equal standards have arranged for reciprocity on two different bases: (1) On the basis of an examination before an examining board, and (2) on a diploma without an examination.

1. On the Basis of an Examination.—This basis is acceptable to a larger number of states than the second. A physician must have passed an examination before an examining board and (under most provisions) have resided in that state a year succeeding the examination, whereon he may register in any other state of the group through reciprocity without examination.

2. On the Basis of a Diploma Without Examination.—This applies only where the applicant was registered in another state prior to the date when the state receiving him through reciprocity required an examination. For example, a physician of good repute was registered to practice medicine in Nebraska in 1880. For good reasons he desires to change residence to Minnesota. Taking for granted his credentials were otherwise acceptable, he is eligible to registration in that state through reciprocity, since Minnesota did not require examination of all applicants until Jan. 1, 1887. Those who registered in Nebraska since Jan. 1, 1887, would not be eligible through reciprocity unless they could register on Basis No. 1.

The reciprocity table published herewith is based on statements from the various examining boards and other data, which we have reason to believe is reliable. The figures given on the table indicate (1) whether reciprocity is on the basis of an examination, and (2) whether reciprocity is on either the basis of an examination or on a diploma without examination. In the table are a number of states which apparently do not reciprocate with others, although having authority under their laws to do so. In regard to reciprocity with these, one should refer to the special statements below regarding reciprocity with these states.

While the various states reciprocate, as stated in the table, most of them have other requirements. All of them require that the applicant must be of good moral character and that he shall hold credentials from a recognized medical college. Many require one or two years of reputable practice, and some require that he must have been a member of a county, state or national medical society for at least a year. Regarding these special requirements one should correspond with the secretary of the examining board of the state where he wishes to locate.

The laws of the following states have provisions for reciprocity, but no information is at hand as to what arrangements have been made with any states in regard to it:

California.—"The board may, in its discretion, accept and register, on payment of the registration fee, and without examination of the applicant, any certificate which shall have been issued to him by the medical examining board of the District of Columbia, or of any state or territory of the United States; provided, that the legal requirements of such board shall have been, at the time of issuing such certificate, in no degree or particular less than those of California at the time when the certificate shall be presented for registration to the board created by this act; and provided, further, that the provisions in this paragraph contained shall be held to apply only to such of said medical examining boards as accept and register the certificates granted by this board, without examination of them, of the ones holding such certificate." The registration fee is $20.00. California does not yet reciprocate with any other state.

Colorado.—It is the policy of this board to license without examination applicants who have been legally engaged in the practice of medicine in other states, provided they qualified in those states by offering in evidence a standard of educational and moral qualification which was required in Colorado for the corresponding year. This board will also register without examination all applicants who have been admitted and are duly authorized and empowered to practice medicine in any of the regular medical departments of the Army, Navy and Public Health and Marine-Hospital Service of the United States of America, and who are in good standing and of good repute in such Federal service.

Connecticut.—The license granted by any other state may be accepted on presentation of satisfactory evidence that said license was granted after an examination equivalent to that of the Connecticut board.

Delaware.—The board indorses the certificate of license issued after examination by any state medical examining and licensing board whose standard of requirements is substantially the same as that of Delaware or higher, irrespective of reciprocity, provided the applicant furnishes satisfactory proof of good moral character. Reciprocal registration fee, $50.00.

District of Columbia.—The board is authorized to license, without examination, any applicant who has been engaged in the practice of medicine and surgery in any other state, territory or insular possession of the United States or a foreign country for the last two years, and who received his license under conditions equivalent to those required in the District of Columbia; provided, that the licentiates of the district board are granted a similar privilege.

Kansas.—The board may accept the certificate of the board of registration and examination of any other state or territory or any foreign country whose standards of qualification for practice are equivalent to those of this state.

Maine.—Any person who is eligible for examination before this board, and who has been examined and registered or licensed by the examining board of any other state which maintains a standard of education at least equal to that required in this state, may be registered on complying with the requirements of the board.

Missouri.—The legislature passed a reciprocal clause granting us the privilege to hold reciprocal relation with states having a standard of requirements equal to the requirements of this state.

New Hampshire.—Applicants examined and licensed by other state examining boards registered by the regent as maintaining standards not lower than those provided by this state, may, on payment of $5.00, be licensed without examination.

New Jersey.—New Jersey will now indorse the medical license issued by any state after examination, whose educational, examining, and licensing requirements are substantially equal to, or higher than those of New Jersey, irrespective of reciprocity, provided the applicant complies with the conditions of indorsement. The fee is $50.00.

New Mexico.—On payment of the regular fee, the board may grant licenses to licentiates of other states and territories which have like requirements, and when said states and territories reciprocate in this matter.

Key: 1, Reciprocates on basis of an examination. 2, Reciprocates on diploma or examination.

South Dakota.—The board is empowered to accept and license on the payment of the regular fee ($20.00), without examination, the holder of a license issued by the examining board of any other state or territory having requirements equal to those of the state of South Dakota at the time when such license is presented for registration, and who grant reciprocal privileges.

Utah is authorized to reciprocate with states having equally high standards.

Vermont.—The board will endorse the certificate or license of any state medical examining and licensing board in accordance with the following section of the Public Acts of 1904: The board shall issue licenses without examination to reputable physicians and surgeons who shall personally appear and present a certified copy of certificate of registration or license, which has been issued to said applicant in another state in the Union, where the requirements for registration shall be deemed by said board to be equivalent to those of this state, provided such state shall accord a like privilege to holders of a license granted under the laws of this state. Each applicant for such license shall pay to the board the sum of $10.00.

Wyoming.—The board may, in its discretion, grant certificates on licenses issued by the medical examining board of the District of Columbia, or of any state or territory of the United States, provided they have been granted on requirements no less than those of Wyoming, and provided, further, that the board of the state or territory issuing the license reciprocates on the same terms with Wyoming.

No Reciprocity.—The following states have made no statement in regard to or no arrangements for reciprocity:

Alabama.
Arizona.
Arkansas.
Florida.
Idaho.
Indian Territory.
Louisiana.
Massachusetts.
Mississippi.
Montana.
North Carolina.
Oklahoma.
Oregon.
Pennsylvania.
Rhode Island.
Tennessee.
Washington.
West Virginia.

EDUCATION NOTES.

New Colleges.

Nine new schools have been organized since June, 1905, five of which had matriculants. These colleges are the College of Physicians and Surgeons, Little Rock, Ark.; the Atlanta School of Medicine, Atlanta, Ga.; the Indiana Medical College, School of Medicine of Purdue University, Indianapolis, Ind.; the State College of Physicians and Surgeons, Indianapolis, Ind.; the Mississippi Medical College, Meridian, Miss.; the Nebraska College of Medicine, Lincoln, Neb.; the Medical Department of the University of North Dakota, University, N. Dak.; the College of Physicians and Surgeons, Memphis, Tenn., and the Medical Department of the University of Utah, Salt Lake City, Utah.

Colleges Which Have Raised Standards During the Past Year.

The colleges listed below, according to their announcements, have made an increase in entrance requirements during the past year:

University of California, two years of work in a college of arts.
University of Missouri, one year in a college of arts.
George Washington University, two years of work in a college of arts, beginning with the session of 1909-10.
University of Texas Medical Department, the equivalent of one year's work in a college of arts, beginning in 1909.

Colleges which have already been requiring one or more years of work in a literary college are the following:

Harvard Medical School requires a degree from a college of liberal arts.
Johns Hopkins Medical School requires a degree.
Western Reserve University Medical Department, three years.
Rush Medical College, two years.
Indiana University Medical School, two years.
University of Minnesota, both regular and homeopathic departments, one year now, will require two years hereafter.
College of Physicians and Surgeons, New York, requires one year.

The faculties of the following colleges have voted to require a preliminary year in physics, chemistry, biology and languages to apply to all students beginning medical study after Jan. 1, 1910:

College of Physicians and Surgeons, San Francisco.
Northwestern University Medical School.
Jenner Medical College.
State University of Iowa, both regular and homeopathic departments.
University of Kansas, Medical Department.
College of Physicians and Surgeons, Baltimore.
College of Physicians and Surgeons, Boston.
Cleveland Homeopathic Medical College.
Cleveland College of Physicians and Surgeons.
University of Tennessee Medical Department.
Dearborn Medical College (evening classes) has extended its course to five years.

The following colleges, according to their announcements, have lengthened their annual sessions as follows:

1. Medical College of Alabama, from six to seven months.
2. University of Arkansas, from six to seven months.
3. College of Physicians and Surgeons, Los Angeles, from eight to eight and one-half months.
4. Denver Homeopathic Medical College, from seven to eight months.
5. Georgetown University, from eight to eight and one-half months.
6. Atlanta College of Physicians and Surgeons, from six to seven months.
7. Atlanta School of Medicine, from six to seven months.
8. Hahnemann Medical College, Chicago, from seven to eight months.
9. Physiomedical College of Indiana, from seven to eight months,
10. Keokuk Medical College of Physicians and Surgeons, from seven to eight months.
11. Maryland Medical College, from eight to nine months.
12. Baltimore University Medical Department, from six to nine months.
13. Detroit College of Medicine, from seven to eight months.
14. Barnes Medical College, from seven to eight months.
15. Western Reserve University, from eight to eight and one-half months.
16. Willamette University, from six to seven months.
17. University of Oregon Medical Department, from seven to seven and one-half months.
18. University of Tennessee Medical Department, from six to seven months.
19. Chattanooga Medical College, from six to seven months.
20. Memphis Hospital College, from six to seven months.
21. Eclectic Medical College of Indiana, from six to seven months.

Distribution of Medical Students.

Table 2. on pages 630 to 633, shows the distribution of students of each college by states. The influence of the proximity of the medical school is seen in the fact that states which have medical colleges have more students in proportion to the population than those which have none. Only three states contributed over 2.000 students: New York, 2,361, Illinois, 2,383; Pennsylvania, 2,115. Two states contributed over 1,000 students, but less than 2,000; Missouri, 1,087, and Texas, 1,026. Ohio contributed 975 students; Massachusetts, 923; Kentucky, 891; Iowa, 828, and Indiana, 815. Of the states having the fewest students, Arizona and Wyoming each had 9. Nevada and New Mexico each contributed 23; Montana, 27; Idaho, 41; Delaware, 54; North Dakota, 61, and South Dakota, 79. The states not mentioned contributed between 100 and 700 each. Only one college failed to furnish the information needed in time for publication. In this instance, that the totals may be more nearly accurate, we have inserted the distribution of last year. All the states from whom no reports were received last year, sent in their reports this time, so our report is practically complete.

Etiology of Abdominal Conditions.—J. Gibbs, in the *Canada Lancet*, June, 1906, traces the etiology of infections of the pancreas, duodenum, stomach, gall bladder and liver to the obstruction and stagnation in the intestines and glandular ducts occasioned by prolapse of the organs following relaxation of the abdominal walls.

Medical News

ARKANSAS.

Personal.—Dr. Joseph P. Sheppard, Little Rock, will succeed Dr. William P. Illing as superintendent of the Pulaski County Hospital on October 31, when Dr. Illing's resignation will become effective.——Dr. George H. Martindale, Hope, is reported to have shot and killed Sam Thomas at Patmos, August 14.——Dr. George S. Brown has been elected president, Dr. George D. Dickerson, secretary, and Dr. Joseph S. Westerfield a member of the Conway Board of Health.

CALIFORNIA.

Banquet to Red Cross Director.—A banquet was given at the St. Francis Hotel, July 31, in honor of Dr. Edward T. Devine, director of the American Red Cross, and after the banquet a silver loving-cup was presented to him by the citizens of San Francisco.

Mortality.—The mortality for June was at an annual death rate of 15.5 per 1,000. Tuberculosis was the chief cause of death, followed by diseases of the circulatory and nervous systems and by pneumonia. The most fatal epidemic diseases in order were typhoid fever, measles, whooping-cough, diphtheria, croup and influenza.

Hospitals to Be Established.—Dr. Winslow Anderson has petitioned for a permit to reëstablish the St. Winifred's Sanatorium at 1025 Sutter Street. He proposes to put up a reinforced concrete building.——The regents of the University of California have planned to establish a students' hospital on the campus at Berkeley.

Personal.—Dr. R. S. Lanterman, Los Angeles, was caught between the step of his carriage and a heavy truck, August 5, and suffered severe contusions of the leg.——Dr. Quinton J. Rowley, Downey, who has been in practice for many years, retired August 1.——Dr. Chester Rowell, Fresno, who has been dangerously ill, is slightly improved.

College News.—The College of Physicians and Surgeons, San Francisco, has petitioned the Board of Supervisors for permission to establish and maintain a medical college at its old address on Fourteenth Street between Woodward Avenue and Stevenson Street.——The regents of the State University, Berkeley, have arranged that the old mining laboratory building is to be used by the department of anatomy and that the other departments of the medical college for the first two years will be housed in the civil engineering building.

Surgeons for Relief Work.—The Board of Health of San Francisco has appointed the following surgeons to take charge of the relief work of the city: Drs. Charles Clark, John A. Haderle. H. V. Prouty, David Friedlander, Herbert A. Gale, Arthur B. Nelson, William J. Gavigan, G. C. Albee, Walter S. Johnson, Emil V. Lonigo, Silvis J. Onesti, Frederick R. Starr, Grace Simon, James V. Hughes, Thomas B. W. Leland, George L. Helms, William C. Hopper, William R. P. Clark, William C. Voorsanger, John M. Quigley, Benjamin Apple, William F. McNutt, Jr., Watts and Roland E. Hartley.

COLORADO.

New Hospital.—The Santa Fé Hospital Association has appropriated $25,000 for the erection of a new hospital at La Junta.

Personal.—Dr. Richard V. Barta, Denver, has been appointed a police surgeon to succeed Dr. Wilbur L. Davis, resigned.——Dr. Raynor E. Holmes, Canon City, who underwent an operation in Pueblo for appendicitis, July 16, is making a satisfactory recovery.

Fined for Failure to Report Disease.—Dr. Chelsea M. Erb, Leadville, charged with having violated the city ordinance, July 31, by failing to report a case of diphtheria within twenty-four hours after its discovery, was found guilty and fined $10 and costs. The case was appealed to the county court.

CONNECTICUT.

Off for Europe.—Dr. William F. Verdi, New Haven, sailed for Europe on the *Kaiser Wilhelm II*, July 17.——Dr. John B. Boucher sailed for Germany, August 4.

July Deaths.—During the month of July, 1,525 deaths were reported, 276 more than for June, 125 less than in July, 1905, and 92 more than the average number of deaths during July for the five preceding years. Infectious diseases caused 119 deaths, or 15 per cent. of the total mortality.

Communicable Diseases.—On August 11. eight cases of typhoid fever were found on a single milk route in New Haven, and on the same milk route five more cases were discovered August 13.——On August 11, six cases of diphtheria were reported from Windsor Locks. The proper quarantine precautions have been taken.

Infectious Diseases.—During July 4 cases of smallpox were reported from 3 towns; 57 cases of measles, with two deaths, from 38 towns; 55 cases of scarlet fever from 24 towns; two cases of cerebrospinal fever. from two towns: 806 of diphtheria, with two deaths. from 22 towns: 92 cases of whooping-cough. with 5 deaths. from 22 towns; 65 cases of typhoid fever. with 4 deaths. from 28 towns: and 58 cases of consumption. from 25 towns. with 23 deaths from the disease.

DELAWARE.

Delaware to Fight Tuberculosis.—The Delaware Anti-Tuberculosis Society has been incorporated and will erect buildings as soon as funds can be secured. Dr. John J. Black is the leader in the movement. The society was organized two months ago at a meeting in Wilmington, when addresses were made by Dr. Lawrence F. Flick. Dr. Joseph Walsh, and other Philadelphians interested in the work. Efforts are being made to raise the money needed for the buildings. and an appropriation by the state legislature is expected next winter. The society will conduct a sanatorium and dispensary for consumptives in the same manner as those at White Haven and elsewhere. It is stated that patients will be cared for in tents until the buildings are completed.

DISTRICT OF COLUMBIA.

Personal.—Dr. John P. Cole. Washington, suffered painful injury by being thrown from his carriage in a runaway. July 28.——Dr. Alfred Richards has been appointed police surgeon of the third surgical district, vice Dr. Charles C. Marbury, resigned.

Less Typhoid.—There was a decrease in typhoid fever in the District during the week ended August 11. in which 72 cases were reported. Since the first of the year 519 cases have been reported. and during the same period of 1905 only 395 cases. There were 26 cases under treatment in Washington August 12.

Health of the District.—During the week ended August 4 there were 139 deaths reported, 76 among the whites and 63 among the colored population, equivalent to an annual mortality of 22.1 per 1,000. The chief causes of death were: Diarrheal diseases. 18, or 3 less than in the previous week; consumption. 15. 1 less than for the preceding week: kidney disease. 10: heart disease. 9; malignant diseases and pneumonia, each 6; typhoid fever and cerebral hemorrhage. each 5. During the week there were 78 new cases of typhoid fever reported and 21 patients were discharged.

GEORGIA.

Personal.—Dr. and Mrs. J. M. Baird, Columbus, sailed for Europe August 21 on the *Kaiser Wilhelm II*.

Provision for Insane Consumptives.—In a bill passed by the house. August 3. provision is made for $10,000 of the last appropriation voted for the State Sanatorium in Milledgeville, to be used for the erection of a building for the isolation of insane consumptives.

Augusta College Notes.—The faculty of the Medical College of Georgia has petitioned the city council for $5.000 to enlarge the municipal laboratory.——Drs. Charles W. Crane, William C. Kellogg. William Z. Holliday and William C. Lyle have been added to the faculty of the college.

Scholarships in Medical Colleges.—The Governor has issued an order naming the following successful competitors for the beneficiary scholarships in the medical colleges of Georgia: State at Large—Frank C. Tharpe. Buena Vista; Frank P. Norman. West Point: W. E. Braswell. Monroe; John A. Brown, Athens; First District—Harry Sutten, Swainsboro; George L. Smith, Swainsboro: Second District—G. T. Crozier. Cedar Springs; Leonard Baker. Ansley; Third District—Guy C. Lunceford. Americus: Jesse H. Riley. Grovania: Fourth District—Thomas Grant. West Point: W. E. Drane. Buena Vista; Fifth District—W. H. Galloway. Monroe; Mason Smith, Douglassville: Sixth District—W. H. Austin. Griffith; George L. Johnson. Yatesville: Seventh District—W. A. Davis. Marietta, R. F. D.: Irby Simmons. Hiram: Eighth District—O. S. Wood, Madison: G. T. Bernard. Athens: Ninth District—J. S. Burrell. Burton: Ralph Freeman. Dacula: Tenth District—John L. Lee. Augusta: L. B. Royal. Hephzibah; Eleventh District—W. T. Price, Jr.

ILLINOIS.

Personal.—Dr. Albert H. Dollear, Jacksonville, has been appointed assistant physician at the Illinois Western Hospital for the Insane, Watertown.

Defies State Board.—John Gregg. Sterling, who has been ordered by the State Board of Health to discontinue practicing massage and magnetic healing on penalty of being prosecuted for violation of the laws, is reported to have written to the State Board of Health that he would continue practicing and that he defied the board to stop him.

Smallpox.—A case of smallpox was reported from Evanston August 12, and the patient, who had come from Michigan a few days before, has been taken to the Isolation Hospital, Chicago.——Smallpox in mild form was discovered by the health officer of Peoria, August 13. Three children in one family were affected, and the entire family, consisting of father, mother and six children, were taken to the Detention Hospital. The disease is believed to have been communicated by a member of the family who recently contracted it in California.——A case of smallpox was discovered in a Chicago hospital August 14. The patient lived in a boarding-house in West Monroe street and had recently visited Milwaukee and Joliet.

Chicago.

Danger of Typhoid Epidemic.—According to newspaper reports residents in the southern part of Chicago are threatened with typhoid because of an official blunder in sewer construction, which has produced a dangerous condition of the drainage. The board of local improvements is constructing a new sewer system on Seventy-ninth street. and it is asserted that instead of building the lateral sewers connecting with the homes at the time the work on the sewers was being done, the contractors cut off the drain pipes leading to the street gutters and there is now no outlet for the waste water and sewage from the homes.

Deaths of the Week.—During the week ended August 18, 531 deaths were reported, 72 fewer than were reported during the week previous. The chief decreases in death causes were in acute intestinal diseases, 25; consumption, 10. and nephritis, 7. There was a sharp increase in the number of deaths from bronchitis, from 3 to 12. The mortality was equivalent to an annual death rate of 13.52 per 1,000. Acute intestinal diseases still led death causes with 125, followed by consumption with 53; violence, including suicide, with 48; nephritis with 42; pneumonia with 27; heart diseases with 25; cancer with 24, and nervous diseases with 20.

INDIANA.

Typhoid Fever.—Numerous cases of typhoid fever of a severe type are reported at Churubusco and vicinity.——The Secretary of the Board of Health of Evansville has analyzed the drinking water of that city and issued an urgent warning against the drinking of unboiled water.

July Diseases and Deaths.—During July diarrhea and cholera morbus were the most prevalent diseases in Indiana. Tonsillitis, rheumatism and dysentery were quite prevalent and there was a decrease in typhoid fever, as compared with July, 1905. There were reported 18 cases of smallpox from 7 counties. with 1 death. Tuberculosis caused 319 deaths during the month: cancer caused 108 deaths; pneumonia was much lessened as compared with the preceding month. Deaths from violence numbered 208, of which 7 were homicides, 13 suicides, and 188 accidental. Of the latter. 36 occurred on steam railways and 4 on the street cars. Burns and scalds caused 18 deaths. drowning 32, ptomain poisoning 3, poisoning 5, suffocation and lightning each 7, sunstroke 8, and mining accidents 6.

KANSAS.

Typhoid Fever.—Six cases of typhoid fever have been reported in Topeka, the largest number thus far reported in a single month.

Ill in Leavenworth.—Dr. William R. Van Tuyl, county physician of Leavenworth County, is ill at his home in Leavenworth.——Dr. Harley J. Stacey, Leavenworth, is suffering from septicemia.

Tuberculosis Census Planned.—The State Board of Health is endeavoring to secure as nearly a complete census of the tuberculosis in the state as possible. To each of the physicians in the state blanks will be sent for the report of the cases in his practice. The blanks also show the stage of the disease, the causation. and the previous general health of the patient.

LOUISIANA.

State Board of Health Moves.—The State Board of Health has taken a suite of rooms in the Hibernia Building, New Orleans, which will be ready for occupancy about October 1.

Typhoid Fever.—Owing to the numerous cases of typhoid fever at New Iberia, the milk supply has been placed under rigid examination and the character of the water supply is also being investigated.

Polyclinic and College Merged.—It is stated by the New Orleans *Democrat* that the arrangements have been practically completed for the merging of the New Orleans Polyclinic and Tulane University of Louisiana.

Personal.—Dr. J. Ashton Blanchard has been elected city health officer and president of the Shreveport Board of Health. ——Dr. A. H. Butler, New Orleans, has been appointed resident medical inspector at Tela, Honduras.

Hospital Notes.—At a regular meeting of the managers of the Truro Infirmary, it was decided to screen thoroughly the entire building, which is now in course of completion.——A sanitarium is to be built at Shreveport, to cost about $20,000.

Chagres Fever at Quarantine.—The steamer *Whitehall*, which arrived at Quarantine from Colon August 4, lost three of her complement of 21 men from chagres fever. The steamer was declared to be a menace to all ports and orders were given by the State Board of Health to hold it indefinitely at the Mississippi River Quarantine station.

Yellow Fever.—On August 19, Dr. Clifford E. Irion, Benton, president of the State Board of Health, sent out an announcement of a case of yellow fever at New Iberia, 125 miles from New Orleans. The patient was a mulatto boy, 12 years of age, living in an isolated part of the city. Dr. Irion has gone to New Iberia to take charge of the situation.

Seeks Information.—The State Board of Health is making every effort to secure as accurate and as reliable information as possible from the practitioners in the state regarding all cases of yellow fever. Circular letters have been sent to all physicians and parish health officers enclosing blank forms and asking them to report to the State Board of Health all cases of yellow fever in their practice.

Epidemic at Sabine Parish.—Dr. Fred J. Mayer, a special medical inspector of the State Board of Health, is investigating a peculiar infection in Florien Sabine, where an epidemic of spinal meningitis was reported, with a mortality of 90 per cent. Dr. Mayer considers the epidemic to be typhoid fever, and says that the death rate, which amounted to about 50 per cent., was the result of excessive doses of quinin and calomel.

Injunction Issued.—The State Board of Medical Examiners on August 13, filed a suit against D. N. Williams, New Orleans, claiming that he was practicing medicine without having first obtained a certificate as the law requires. Under the law, if Williams has been practicing medicine without warrant of law, he is liable to $100 fine and $50 attorney's fees. In the suit filed, an injunction was asked to restrain Williams from practicing medicine until he should have obtained a certificate, and Judge St. Paul ordered the issue of the injunction.

MARYLAND.

Baltimore.

Personal.—Dr. William E. Hoffman has been appointed city chemist, vice Dr. Gustav W. Lehman, deceased.——Dr. Alexander D. McConachie is taking a trip to Nova Scotia, New Brunswick and Newfoundland.——Dr. Joseph G. Evans, formerly of Baltimore, now assistant quarantine officer at Cristobal Colon, Canal Zone, is visiting his home in Marion, S. C.

Donation to Hospital.—The widow of the late Dr. Samuel L. Frank, who was the president of the Hebrew Hospital at the time of his death, will donate $75,000 to that institution to be used in the erection of a new hospital building adjoining the present one. The new building will be made the hospital proper and the present building will be used as a home for incurables and as a training school for nurses.

MASSACHUSETTS.

New Floating Hospital.—The new floating hospital sailed August 15, on her first trip with 80 permanent and 110 day patients aboard. Dr. Robert W. Hastings, resident physician of the hospital, is in charge of the boat. The cost of the boat, fully equipped, has been about $100,000.

Personal.—Dr. William J. Sullivan has resigned as trustee of the pauper institutions of Boston at Long Island. Dr. David D. Scannell and the other trustees, whose resignations were asked for by the Governor, it is reported, refused to resign, and were removed.——Dr. Frederick G. Smith, Summerville, has returned from Germany.

MICHIGAN.

Forbidden to Distribute Samples.—The authorities of Pontiac has forbidden the distribution of samples of patent medicines and circulars.

Personal.—W. L. Shuart, Battle Creek, has been appointed a member of the board of preliminary examiners for admission to medical colleges by the State Board of Registration in Medicine.——Dr. and Mrs. Alexander G. McLeod, Calumet, left for Scotland August 1.——Dr. James A. Ardiel, Grand Rapids, has returned from a two-months' trip to Great Britain.

Northern Michigan Physicians Meet.—At the annual meeting of the Upper Peninsular Medical Society, held in Escanaba, August 2 and 3, Menominee was decided on as the place for the next meeting, and the following officers were elected: President, Dr. Alfred F. Snyder, Escanaba; vice-presidents, Drs. Benjamin T. Phillips, Menominee and Charles H. Rodi, Calumet; and secretary, Dr. Robert A. Walker, Menominee.

Coroners Should Be Physicians.—At the annual meeting and picnic of the Ottawa County Medical Society, July 25, a decided stand was taken in favor of the position of coroner being held only by medical men, and the following resolutions were unanimously adopted, to be presented to the Republican County convention:

> The Ottawa County Medical Society wishes to impress on the public and on the county conventions, both Republican and Democratic, that in accordance with the proper performance of the duties of coroner, and especially for the public good, the office of coroner should be filled by a medical man, one fully conversant with medicolegal matters, necessary for the proper understanding of this office. As physicians of Ottawa County and as citizens who have always worked for the good of the people, the medical fraternity suggests that the nominations for the office of coroner be filled with the names of representative physicians instead of laymen.

MISSISSIPPI.

Fire Damage.—At a fire in Moorhead, July 2, Dr. W. A. Attaway suffered a loss of $3,000, partially covered by insurance.

New Hospital.—The Board of Trustees of the Mississippi Insane Hospital, Meridian, at its regular meeting, considered plans for two new hospital buildings, to be erected at a cost of $30,000.

Favorable Health Report.—On August 3, Dr. John F. Hunter, Jackson, Secretary of the State Board of Health, reported that the general health conditions of the state were never better at this period of the year. From no part of the state was contagious or infectious diseases reported, with the exception of a few cases of scarlet fever.

Medical College Officers.—The following are the officers of the Mississippi Medical College, which is to be opened about October 1: President, Dr. W. W. Hamilton; vice-president, Dr. T. A. Barber; secretary, Dr. O. W. Bethea; treasurer, Dr. T. J. Houston, and dean, Dr. N. L. Clarke, and these officers constitute the executive committee. The following have been elected members of the faculty of the institution: Dr. N. L. Clarke, dean and professor of diseases of children; Dr. W. W. Hamilton, obstetrics and clinical genitourinary diseases; Dr. D. U. Wadsworth, surgery; Dr. J. H. Blanks, operative and clinical surgery; Dr. W. W. Reynolds, anatomy; Dr. M. J. Lowrey, gynecology; Dr. O. W. Bethea, pharmacology; Dr. H. F. Tatum, chemistry; Dr. W. J. Anderson, physiology and clinical gastrointestinal diseases; Dr. J. R. Tackett, theory and practice of medicine; Dr. W. H. Rowan, physical diagnosis and chest diseases; Dr. T. A. Barber, eye and ear; Dr. J. E. Seale, nose and throat; Dr. T. J. Houston, genitourinary surgery and venereal diseases; Dr. F. L. Walton, clinical medicine and clinical eye, ear, nose and throat. Lecturers and instructors: Dr. Saro Castle, bacteriology, hygiene and clinical dermatology; Dr. C. H. Ramsey, pathology, histology and electro therapeutics; Dr. James Bennett, demonstrator of anatomy and clinical lecturer on diseases of children; Dr. E. E. Robinson, clinical gynecology, minor surgery and surgical dressing; Dr. S. A. Witherspoon, medical jurisprudence.

NEW JERSEY.

Hospital Incorporated.—Incorporation papers have been filed for the Newark Private Hospital, with a capital of $50,000.

Anti-Tuberculosis Society.—A branch of the Association for the Prevention and Relief of Tuberculosis was organized in Camden, August 15, at the office of the mayor.

Typhoid Fever.—The seventeen cases of typhoid fever which were reported at Trenton for the week ended August 11, have been traced to one dairy, the owner of which was suffering from the disease. The Board of Health is making thorough plans for the inspection of milk in the city.

Personal.—Dr. Edmund Eastwood, Burlington, has resigned as city physician and Dr. Charles Dingee has been appointed to fill the vacancy.——Dr. Claude E. McNenney, Jersey City, was severely injured in a panic on the excursion steamer *Perseus* July 19. He was severely bruised and had one of his lower ribs fractured.——Dr. William O. Bailey, Newark, was thrown from his carriage in a runaway accident, August 9, and sustained severe lacerations and contusions and injuries of the right hip.

NEW YORK.

New York City.

Foul Bakeries.—The health board in its recent investigation has found 229 insanitary bakeries.

Personal.—Dr. J. Hubley Schall sailed on the *Minneapolis* August 18.——Dr. William T. McMannis returned last week from Europe.

Ellis Island Epidemic.—Trachoma has been unusually prevalent at Ellis Island, 127 immigrants having been deported on account of this disease during the first two weeks of August.

Public School Nurses.—In 1905, the Health Department spent $60,000 for nurses employed in public school and tenement-house work. An allowance of $55,000 has been made for the same purpose for the present year.

NORTH CAROLINA.

Typhoid Epidemic at Elizabeth Seminary.—Passed-Assistant Surgeon Anderson of the Public Health and Marine-Hospital Service, has completed his investigation of the typhoid fever epidemic which occurred in May at Elizabeth Seminary, Charlotte. The school has 180 pupils and teachers, 92 of whom boarded in the college, of these 33 developed a supposed enteric fever within the ten days from May 10 to May 20. Dr. Anderson thinks (*Public Health Reports*) that only 17 of these were genuine typhoid, since the other cases had a duration of less than a week. None of the day pupils, about 88 in number, developed enteric fever during this time. The epidemic seems to be traceable to an additional supply of milk which was first used at the college twenty-one days before the outbreak of the fever. Practically the entire water supply of the city of Charlotte is infected, apparently in consequence of the presence of cases of enteric fever on the watershed, and the unscientific and faulty method of conducting the filtration plant, which removes only about 88 per cent. of the bacteria. Bacteriologic and chemical study of the water supply, proper policing of the watershed, daily examinations of the water, closure of infected springs and wells, the regulation of the milk business and the ice industry, sterilization of milk bottles and utensils are recommended. It is suggested that ice ought not to be put directly into milk or drinking water. If these suggestions are carried out Dr. Anderson states that parents need have no hesitancy in sending their daughters to Elizabeth College for the ensuing session.

NORTH DAKOTA.

Personal.—Dr. Henry H. Ruger, Devil's Lake, one of the pioneer practitioners of North Dakota, had a severe cerebral hemorrhage a few days ago, but is now reported to be slowly improving.

District Medical Society Meeting.—The annual meeting of the Grand Forks Medical Society was held in Grand Forks, July 11, and the following officers were elected: Dr. Frank J. King, St. Thomas, president; Dr. James Grassick, Grand Forks, vice-president; Dr. Henry H. Healy, Grand Forks, secretary; Dr. Archie L. McDonald, Grand Forks, treasurer; Drs. W. H. Bates and Charles S. Crane, Grand Forks, delegates to the state society, and Dr. Charles A. Warner, Petersburg, censor.

OHIO.

Submit Plans for Tuberculosis Hospital.—The State Tuberculosis Hospital Commission met August 14 and considered the plans for the hospital submitted for their approval.

Free Antitoxin.—The State Board of Health has issued a circular to the boards of health and the officers regarding the free issue of antitoxin for the protection of the public health. The State Board has arranged to keep a stock of fresh antitoxin always on hand, and a supply will be sent immediately to any board of health on request.

Personal.—Dr. Joseph A. Stansell, Forest, is critically ill with nephritis and prostatitis.——Dr. Otto Juettner, Cincinnati, has been made an honorary member of the Roentgen Society of Breslau, Germany.——Dr. Philip S. Rieg, Toledo, has been appointed medical examiner for the U. S. Marine Corps for that district.

OREGON.

Medical School Remodeled.—The Medical Department of the University of Oregon, Portland, is to be remodeled at a cost of $3,000.

Spotted Fever.—Two serious cases of spotted fever are reported from the sheep country, one at Ironside and the other at Lockhard ranch.

Fire at State Hospital.—A fire at the Oregon State Insane Asylum, Salem, caused damage amounting to about $5,000, July 27. The fire was confined to one ward and owing to the fact that the patients had been given a weekly fire drill, they were marched quickly out of the building without casualties.

Personal.—Dr. Willis B. Morse, Salem, has been appointed a member of the State Board of Health, vice Dr. Harry M. Lane, Portland, resigned.——Dr. Oregon C. Blaney, Portland, had an attack of vertigo recently and fell, sustaining severe lacerations of the face.——Dr. Frederick Crang, Forest Grove, is reported to be critically ill.

Annual Report of Board of Health.—The State Board of Health of Oregon reports that during 1905 there were 3,066 deaths in the state, of which 486 resulted from communicable diseases. There were 4,439 births, of which 2,294 were males and 2,145 females. There were 645 deaths from diphtheria reported, 44 deaths from tuberculosis, and 83 from typhoid fever; smallpox was present at no time during the year to any alarming extent. During the year there were reported 375 cases of typhoid fever, 352 of diphtheria, 338 of measles, 265 of scarlet fever, and 133 of smallpox.

Hospital Notes.—The citizens of Forest Grove have formed a hospital association with Dr. Edgar H. Brown as president, and have decided to establish a hospital in that place. The association is to be incorporated with a capital stock of $5,000.——Drs. W. William Oblesby, and Best, Cottage Grove, are to establish a hospital at Drain.——St. Mary's Hospital, Albany, established by the Sisters of Charity of San Francisco in the Father Metayer mansion, with accommodations for twenty patients, will be opened September 1.——The new hospital at Milton was opened July 30, with appropriate ceremonies.

PENNSYLVANIA.

Personal.—Dr. Daniel B. D. Beaver, of Reading, sailed for Europe August 18.

School Teachers Vaccinated.—The Red Lion School Board has decided that all teachers employed in the borough schools must be successfully vaccinated before the opening of the public schools in September.

Typhoid at Pottsville.—Several cases of typhoid fever have been reported in Fishback, a suburb of Pottsville, and an investigation instituted by the State Department of Health to discover the origin of the infection found it in the water supply.

Site Chosen for Asylum.—The commission for the erection of the Pennsylvania State Institution for the Care and Treatment of the Criminal Insane, have decided on the site at Fairview, Wayne County. This land, comprising 625 acres, 2,000 feet above the sea level, was offered to the commission by the Delaware and Hudson Railroad Company, for $5, the cost of a deed. This is a saving to the state of $9,995 out of an appropriation of $10,000. The commission has the sum of $150,000 toward the erection of the buildings.

Restrained from Practice.—In a decree handed down by Judge Doty, Edward Barnes, Monessen, is restrained from practicing medicine in Westmoreland County. The Medical Association of Monessen made an investigation on a petition presented to it alleging that Barnes had never been a regular practitioner and that he had served a sentence in the state penitentiary for arson. The commissioner who was appointed to take the testimony recommended that Barnes' registration be set aside. It is understood that Barnes is now in Newcastle.

Societies Meet.—The Northwestern Medical Society held its fourth annual meeting at Warren, July 10. The following officers were elected: President, Dr. Morris S. Guth, Warren; vice-presidents, Drs. William A. Nicholson, Franklin; George B. Kalb, Erie; and Thomas L. Kane, Kane; secretary, Dr. James R. Durham, Warren; treasurer, Dr. Charles W. Schmehl, Warren.——The Lehigh Valley Medical Society, at its annual session at Easton, elected the following officers: Dr. Charles McIntyre, Easton, president; Dr. George W. Guthrie, Wilkesbarre. A. F. Myers, Blooming Glen, John H. Wilson, Bethlehem, and Obadiah H. Sproul, Flemington, N. J., vice-presidents; Dr. Clinton J. Kistler, Lehighton, secretary; Dr. William

Dr. Robert Kelly Library
[illegible]

P. Walker, South Bethlehem, assistant secretary; and Dr. Albert A. Seers, Bangor, treasurer.——At the annual meeting of the Montour County Medical Society, the following officers were elected: President, Dr. William H. Krickburn; vice-presidents, Drs. George A. Stock, Robert S. Patten; secretary and reporter, Dr. Cameron Schultz; corresponding secretary, Dr. Ida M. Ashenhurst; treasurer, Dr. Philip C. Newbaker; and censors, Drs. Philip C. Newbaker, Hugh B. Meredith and Edwin A. Curry, all of Danville.

Philadelphia.

Vital Statistics for July.—The report of the division of vital statistics shows that there were reported 2,786 deaths, 2,672 births, and 1,470 marriages during July.

Personal.—Dr. John W. Luther sailed for Europe August 18. ——Dr. and Mrs. Lewis H. Adler, Jr., have returned home after an extensive tour of the Northwest and Alaska.——Dr. Frederick P. Henry has sailed for Europe.

Public Baths Popular.—The hot weather in the early part of last week resulted in the largest attendance of the season at the public baths maintained by the city. The total number of bathers in the week were 677,842, of which 144,313 were men, 7,110 women, 502,652 boys, and 23,767 girls.

Bequests.—By the will of the late Abraham Reinheimer, contingent on the death of two brothers, $2,500 is to be distributed as follows: One-third to the Jewish Hospital, one-third to the Jewish Foster Home, one-sixth to the Jewish Maternity Association, and one-sixth to the Young Women's Union.

Medical Inspection for July.—The report of the Division of Medical Inspection of the Bureau of Health for July shows that for the month all inspections made, excluding schools, were 3,002; 355 fumigations were ordered, 148 cultures taken, 16 examined for special diagnosis. There were 89 injections of antitoxin made, and 151 vaccinations performed.

Bacteriologic Laboratory Report.—The report of the bacteriologic laboratory of the Bureau of Health for July shows that 666 cultures were examined for diphtheria bacilli, and that 426 specimens of suspected typhoid blood were examined. There were also examined 655 specimens of milk, and 100 specimens of sputum; 1,542.500 units of antitoxin were supplied, 10 disinfection tests were made, and 94 analyses were performed.

Increased Accommodations for Blockley.—Director Coplin of the Department of Public Health and Charities opened bids for beds, bedding, plumbing and other necessaries to accommodate 800 additional patients in the Philadelphia Hospital, money for which is to be taken from an appropriation of $126,000 made by council for fitting up the quarters in the Museum Building, to which about 800 paupers have been transferred. Repairs will also be made in the clinic room of the hospital and adjoining grounds.

Candy-Makers Held.—At the instance of B. H. Warren, State Dairy and Food Commissioner, twenty candy manufacturers of this city were arrested August 10 on the charge of selling impure candy and held in bail, ranging from $600 to $1,000. The firms were specifically charged with selling glucose, adulterated with sulphur dioxid and other injurious chemicals. Analysis of samples of grape sugar, made by Professor Lowoll, showed the material to contain an amount of sulphur dioxid exceeding the maximum quantity allowed by the German government in the preservation of fruits. It was concluded, therefore, that the substance was injurious to health.

Insane Patients Increase.—According to W. M. Late Coplin, director of the Department of Health and Charities, the most recent statistics show that the number of insane patients cared for by the city during the past year has increased 7 per cent. This, it is found, is about the same increase as is found in and reported by other cities of the first class. At present the Philadelphia General Hospital is caring for 1,600 insane patients. The average weekly cost per patient is $2.76; of this amount $1.17 is paid by the city and $1.59 by the state. The report shows an increase of 109 over the preceding year, and the total increase during the past decade, Dr. Coplin states, is 75 per cent. During the past 13 years the increase in this city is about the same as is found in other cities in proportion to its population.

Health Report.—The report of the Bureau of Health shows a decrease in the number of deaths from all causes, although the current week's figures are in excess of the same period last year. The total number of deaths for the week were 498, as compared with 519 reported last week, and 438 during the corresponding week of 1905. The principal causes of death were: Typhoid fever 15; whooping-cough, 12; tuberculosis, 57; cancer, 12; apoplexy, 10; heart disease, 31; acute respiratory diseases, 22; diarrhea, 107; cirrhosis of liver, 6; appendicitis, 4; Bright's disease, 26; premature birth, 16; debility, 22; old age, 5; heat, and sunstroke, 8; traumatism, 12; and marasmus, 9. There were 189 cases of contagious disease reported, with 19 deaths, as compared with 154 cases and 21 deaths the preceding week.

Hospital Report.—During July 76 patients were admitted to the Methodist Episcopal Hospital. In the dispensary there were treated the following cases: Medical, 57; surgical, 533; gynecological, 9; eye, 87; ear, 27; nose and throat, 37; skin, 38; orthopedic, 7; and pediatric, 23. The total number of patients treated was 818; total visits to the dispensary, 3,271; recent accidents, 363; patrol cases, 8; and ambulance calls, 22. ——During July 56 patients were admitted to the Mount Sinai Hospital, which with the 26 patients under treatment at the beginning of the month, made a total of 82 treated. There were 37 discharged cured, 5 improved, 4 not improved, 1 left without permission, and 5 died, leaving 30 patients under treatment at the end of the month. In the out-patient department 3,837 visits were paid, 1,407 of this number being new patients; 260 of the new patients were medical, 444 surgical, 144 eye, 75 nose, throat and ear, 237 children, 73 skin, 24 nervous diseases, and 48 gynecological; 466 cases were treated in the emergency ward, 39 being patrol cases and one ambulance case.

WISCONSIN.

Goes Free.—Dr. George T. Dawley, New London, who has been held under bonds on the charge of having performed a criminal operation, was discharged at the hearing August 1.

New Officers.—At a meeting of the Second District Medical Society, held at Kenosha, August 16, Dr. Wiliam A. Fulton, Burlington, was elected president; Drs. William R. Cheever, Kenosha, and George H. Young, Elkhorn, vice-presidents and Dr. J. Russell Eastman, Kenosha, secretary. The next meeting of the society will be held in Burlington.

Personal.—Dr. Alexander Kremers, house physician at the Johnstone Emergency Hospital, Milwaukee, has resigned, and Dr. Oscar Lotz has been appointed temporarily in his place.—— Dr. John A. Rice, Merton, is reported to be seriously ill at his home.——Dr. Gustav A. Hipke, Milwaukee, has been appointed obstetrician of the Milwaukee Maternity Hospital.——Dr. Horace E. Mann, Marinette, has disposed of his interest in the Menominee River Hospital.

Rodermund Again.—Dr. M. J. Rodermund, formerly of Appleton, who received considerable notoriety five years ago on account of his spectacular attempt to prove that smallpox was not contagious, has reopened his "campaign of education," and has written to the Health Commissioner of Milwaukee asking that the city take immediate steps to get the present health laws repealed so that vaccination and quarantine would no longer be required. The health commissioner, very properly, has referred his communication to the editor of the official journal of the Wisconsin State Medical Society.

GENERAL.

Association of Seaboard Air-Line Railway Surgeons.—More than a hundred members of this association attended the annual session in Savannah, July 13 and 14. The following officers were elected: President, Dr. William A. Monroe, Sanford, N. C.; vice-presidents, Drs. James G. Wallace, Dade City, Fla., Hillory M. Wilder, Charlotte, N. C., and Everard H. Richardson, Atlanta, Ga.; secretary and treasurer, Dr. Jarrett W. Palmer, Ailey, Ga. (reëlected), and member of the executive committee, Dr. John H. Miller, Cross Hill, S. C. The 1907 meeting will be held at the Jamestown (Va.) Exposition at a date to be decided later.

Back Numbers of The Journal Wanted.—The entire editions of The Journal for July 14 and July 21 have been exhausted, and it would be a favor if any who do not wish to preserve their copies will send them to the American Medical Association, 103 Dearborn avenue, Chicago. To those who wish it, we will send another copy in exchange or will refund 10 cents for each copy sent. The name and the address of the sender should be on the wrapper.

Ophthalmologists To Meet.—The eleventh annual meeting of the Academy of Ophthalmology and Oto-Laryngology will be held at the Oakland Hotel, St. Clair, Mich. (fifty miles from Detroit), August 30 to September 1, under the presidency of Dr. Casey A. Wood, Chicago. The subjects on the program include lingual thyroids, various uses of paraffin, the uselessness of the spray and the electric cautery for the rhinologist, how to obtain reliable replies by letter from patients, maxillary sinus operations, middle-ear suppuration, oral and laryngeal tuberculosis, cleft palate, tonsilectomy, massage and electricity in atrophy of the optic nerve, eyestrain and crime, cataract extraction, etc. Some addresses will be given by visitors from England who are in this country to attend the British Medical Association meeting this week. Dr. Eugene Smith, Detroit, is chairman of the committee on arrangements.

Mississippi Valley Meeting.—The next meeting of the Mississippi Valley Medical Association will be held at Hot Springs, Ark., November 6-8, under the presidency of Dr. J. H. Carstens, Detroit. The annual address in medicine will be delivered by Dr. Frank Parsons Norbury, Jacksonville, Ill., on "Clinical Psychology," and the address on surgery by Dr. Florus F. Lawrence, Columbus, Ohio, on "Surgical Principles and Theories." The preliminary program shows an excellent series of papers on a wide variety of practical subjects by men from all parts of the Mississippi Valley. Communications should be addressed to the secretary, Dr. Henry E. Tuley, 111 West Kentucky street, Louisville, Ky.

CANADA.

Personal.—Dr. George A. Peters, professor of surgery in the University of Toronto and colonel of the Toronto Light Horse Brigade, is in England, where his recently invented self-recording target is attracting much attention from military experts.

Novia Scotia Society Meeting.—The fifty-third annual meeting of the Medical Society of Nova Scotia was held at Lunenburg, July 3 and 4. The following officers were elected for the ensuing year: President, Dr. J. B. Black, M.P., Windsor; vice-president, Dr. J. A. Sponagle, Middleton; second vice-president, Dr. W. H. McDonald, Rose Bay; secretary-treasurer, Dr. J. R. Corston, Halifax.

British Columbia Association Meets.—The seventh annual meeting of the British Columbia Medical Association was held in New Westminister, August 1 and 2. The attendance was representative from all over the province. The following were the officers elected: President, Dr. R. L. Fraser, Victoria; vice-president, Dr. J. M. Pearson, Vancouver; secretary, Dr. R. Eden Walker, New Westminister; treasurer, Dr. J. D. Helmcken, Victoria. It was decided to meet in Victoria in 1907.

BRITISH MEDICAL ASSOCIATION.

(From Our Regular Correspondent.)

As we go to press a great gathering of medical men is taking place in Toronto. The annual meeting of the British Medical Association is this year held there. Mr. Guy Elliston, secretary of the British Medical Association, who arrived in that city August 10, felt that conditions indicated that there would be held one of the best meetings in the history of the organization. Certainly the indications were that it would largely outstrip the Montreal meeting, when the organization before met in Canada. Dr. Dawson Williams, editor of the *British Medical Journal*, accompanied by a staff of stenographers, arrived in Toronto last week to take charge of the daily publication of the proceedings. A very fine and elaborate exhibit of instruments, pharmaceuticals, etc., was arranged under charge of Dr. Arthur Jukes Johnson. This was in the main building of Toronto University in the Queen's Park, and here also were located the offices of the secretary, treasurer, etc. The general information bureau was also located on the main floor of the building near the entrance. The president of the association, Dr. George Cooper Franklin, will be the guest of Dr. Arthur Jukes Johnson while in Toronto, they having been college mates together many years ago. Sir Victor and Lady Horsley are to be the guests of Dr. H. A. Bruce. There is an unusually large attendance of physicians from the United States. The Journal has several official representatives there and will publish a full report. As we outlined a few weeks ago, physicians from the United States have almost the lion's share of representation in the scientific proceedings, as the program of nearly every section shows. This is an unusual opportunity, nevertheless, to taste the particular British flavor which the meeting will have, and to compare its various aspects with those of the medical gatherings on this side of the line.

FOREIGN.

Swedish Committee for Cancer Research.—The Swedish Medical Association (*Svenska Läkaresällskapet*) has appointed a committee to make a special study of all matters concerning cancer. Prof. J. Berg of Stockholm has been made chairman.

Prizes for Antimalarial Measures.—The Italian government has given prizes of $100 each to five large landed proprietors who have taken pains to have the dwellings of their laborers thoroughly screened against mosquitoes. The list includes Prince Borghese and Countess Lecca.

New Edition of the German Pharmacopeia.—The German authorities have undertaken the revision of the Pharmacopeia and appeal to all interested to offer suggestions for the new edition. Communications should be sent to President Bumm of the Imperial Board of Health, Berlin.

Physician Appointed Warden of Penitentiary in Germany.—The physician hitherto in charge of the insane department of the penitentiary at Münster, Dr. Pollitz, has recently been appointed warden of the penitentiary at Düsseldorf, the first time in Prussia, it is said, that a medical man has been appointed to a post of this kind.

French Congress of Surgery.—The nineteenth annual congress of the French Société de Chirurgie is to be held at Paris, opening October 1. Three questions have been appointed for discussion: "Surgery of the Nerve Trunks," "Ectopia of the Testicles and Its Complications," and "Routes and Means of Access to the Thorax from the Operative Standpoint."

Protection of Medical Experts in Judicial Debates.—A recent decision of a Paris court declares that medical experts summoned by the court are "citizens charged with a public service," and as such come under the special protection of the law. The court condemned to fifteen days in prison an individual convicted of insulting the experts in a recent case before the Court of Appeals.

Degrees Conferred at Greifswald.—On the occasion of its four hundred and fiftieth anniversary, the university of Greifswald conferred honorary medical degrees on Dr. W. W. Keen, Philadelphia; H. Snellen, the Utrecht ophthalmologist; and E. Roux, director of the Pasteur Institute, Paris. An honorary degree in the department of philosophy was also conferred on Krehl of Strasburg. Other details of the celebration were mentioned recently on page 519.

Course in Practical Disinfection.—The authorities in Bavaria are much gratified with the success of a special course of lectures and demonstrations given this summer at Erlangen for physicians and others interested in the practical application of disinfection for houses, halls, etc. Twenty-seven persons took the course, including three physicians. The lectures were delivered by Professors Heim and Weichardt. Kirstein's quiz "Guide for Disinfectors" was recommended as the manual for study.

Medical Advertising in a Rhine Province.—The medical society at Metz has exerted influence to such effect that the governor of the Province of Lothringen or Lorraine has issued a decree prohibiting all public advertising or recommending of treatment of patients without a personal examination, the so-called distance treatment, and also of all advertising of articles, measures, contrivances or methods designed to serve in the prevention, cure or mitigation of disease in man and animals. At the same time all advertisements relating to sexual matters are forbidden. The *Münch. med. Wochschr.* for August 7 gives the details of the new decree.

Italian Congress of Internal Medicine.—The sixteenth congress of internal medicine will be held at Rome in October. The subjects on the order of the day are "Arteriosclerosis," with addresses by Riva of Parma and Devoto of Pavia; "Affections Resembling Typhoid and Malta Fever," addresses by Gabbi of Messina and Lucatello of Padua, and "Arthritism," to be presented by Castellino of Naples. The committee of organization has issued an appeal to all the medical schools throughout the country asking them to inaugurate research along the lines of these suggested topics, hoping that a large and valuable national contribution may thus be secured for the study of these subjects.

Unification of Formulæ for Heroic Drugs.—The *Semaine Méd.* states that eight countries have agreed to accept uniform formulæ for the preparation of the heroic drugs and have notified the Belgian government to that effect. The list includes France, Germany, Great Britain, Holland, Switzerland, Greece and Luxemburg. The original resolution has been amended to allow the formulæ to be modified to keep pace with the progress of medical and pharmaceutical science. It is hoped that this modification will enable all the powers to accept the unified standards. Great Britain, in expressing its willingness to sign the agreement, stipulated that each of its colonial possessions is to sign, suggest modifications or reject, independently of the mother country.

German Police Supervision of Artificial Mineral Waters.—Recent regulations of the police district of Giessen, Grand Duchy of Hesse, Germany, according to the *Apotheker-Zeitung*, No. 59, 1906, provide for police supervision of the factory and springs from which artificial mineral waters are to be made, for official testing of the chemicals and apparatus, and new tests whenever changes or extensions of the business are to be made. Tests must be made at least once a year. No material injurious to health must be introduced into the water by the chemicals or apparatus, and no lead or untinned copper pipes or vessels shall be used. The cost of regular inspection is borne by the community, but extraordinary inspection and tests must be paid for by the manufacturers. The manufacturer can demand a free certificate of the examinations. The provisions of the regulations are enforced by a fine of $7.50.

Successors to Guyon and Brouardel at Paris.—J. C. F. Guyon, the famous French authority on the affections of the genito-urinary organs, was born on the Ile de la Réunion, in the Indian Ocean, in 1831, and has thus reached the age limit, and is compelled to resign his professorship. Besides publishing an atlas of affections of the urinary passages and various collections of clinical lectures, etc., he has long issued the *Annales d. mal. d. organes génito-urinaires*, a semi-monthly journal and review. He is to be succeeded by his former assistant, Joaquin Albarran, who is also a native of a tropical island, Cuba. His works on tumors of the bladder and tumors of the kidney have won prizes offered by the Académie des Sciences, etc.. and numerous articles have appeared from his pen since his first extensive work on the "Spontaneous Cure of Carcinoma," in 1883. Professor Thoinot, an eminent authority in legal medicine, has been appointed to the chair of this specialty left vacant by the death of Brouardel.

Experimental Inoculation of Man with Syphilis.—On page 1.779 of the last volume, June 9, 1906, THE JOURNAL described Metchnikoff's successful therapeutic prevention of syphilitic infection of monkeys and of a senior in the Paris Medical School, who volunteered for the test, all being inoculated with virulent human material. One hour afterward a salve of one part calomel to three parts lanolin was rubbed into the site of the inoculation for eight minutes. The control animals all developed syphilis, but no traces have appeared on the calomel-treated man or monkeys. The young man is a descendant of Maisonneuve, the famous French surgeon, 1809-1897, and bears the same name. His syphilis experiences form the subject of his thesis, recently handed in. The Paris papers have written up Maisonneuve and his thesis, reproducing his portrait and expatiating on his heroism. Metchnikoff has permitted this early publicity given to the matter. Professors Gaucher and Roger have taken a most decided public stand against generalizing from a single case, warning against the evils liable to follow if the public is lulled into a false security in regard to syphilitic infection before the fact of the possibility of therapeutic prophylaxis is scientifically and definitely established.

Quackery in Germany.—In the *Deutsche Revue* for July (abst. in *Apotheker-Zeitung*, No. 59, 1906), E. Roth gives an array of statistics regarding the growth of quackery in Germany which are very interesting. In 1879 there were in Prussia, with the exception of Berlin, 269 quacks; in 1887, 389; and in 1898, 1,200. In 1876 the proportion of quacks to physicians was 1 to 24; in 1898, 1 to 11. In the capital the proportion in 1879 was 1 to 34; in 1898, 1 to 5. In this enumeration the druggists, midwives, etc., are not included, some of whom give medical advice in an illegitimate way. The circles from which the quacks of Berlin are recruited, according to the statements of Beerwald, are also characteristic. Of 124 men who had announced their occupation as healer, 10 per cent. were laborers, 20 per cent. artisans, 46 per cent. came from occupations concerned with trade and commerce, and only 24 per cent could be credited with more than a primary education. In regard to the female quacks, 58 per cent. were formerly servant girls, 24 per cent. confectioners, 10 per cent. working women 5 per cent. nurses, and 2 per cent. had no occupation. While in the last twenty years the population of Berlin has increased about 61 per cent. quackery boasts a growth of 1.600 per cent. These figures should be taken to heart, should be communicated to others, and a reform inaugurated. The following figures also throw a sidelight on quackery. Of all those engaged in treating disease who carry on their business without medical training, not less than 16.6 per cent. had been previously prosecuted in the courts and fined, indeed, according to Magnus these figures rise in some districts of Berlin to 33 1/3 per cent. Quackery had for its support in 1903 already 38 periodicals, while the *Hygienische Blätter*, the official organ of the German Society for the Repression of Quackery was issued first in 1904, although this antiquackery journal also had certain predecessors. It was described in THE JOURNAL recently on page 453 of the last volume, with the aims and work of the society.

French Congress of Alienists and Neurologists.—The sixteenth annual congress was held at Lille during the first week in August. The official records are published in the *Archives de Neurologie*, but a rather full report has already appeared in the *Semaine Médicale* of August 8. The principal subjects discussed were "The Blood in the Insane," "The Senile Brain," "The Responsibility of Hysterics," "Relations Between Trauma and General Paralysis," and "The Grave Prognostic Significance of the Lympho-Polynucleosis in the Cerebrospinal Fluid in Acute Ascending Spinal Paralysis." Dide of Rennes and Régis of Bordeaux, after describing their cytologic, bacteriologic and experimental researches on the blood of insane patients, come to the conclusion that the function of defense on the part of the blood is materially disturbed in the insane, and in cases of acute or subacute confusional psychoses, such as dementia præcox, general paralysis, etc. This disturbance has considerable pathogenic importance, but it does not seem to be permanent in the majority of cases. It is possible that a severe and protracted intercurrent infection may rearouse this defensive function. They refer to the improvement and even the cures realized by certain physicians who have not hesitated to inject insane patients with attenuated virus for this purpose. Régis advises comparative study of the blood and urine as affording instructive data. Sabrazès of Bordeaux does not believe that nervous disorders affect the composition of the blood to any extent when they are once established. He is convinced that the nerve centers suffice for themselves in the defense against toxi-infections. The leucocytes do not interfere except in certain infections, such as suppurative meningitis, abscess, etc. Several members told of invariably negative findings in examination of the liver, nerve centers, meninges, and blood of syphilitics in the search for the *Treponema pallidum*. Léri remarked in regard to the senile brain that senility and old age are by no means synonymous terms. Also that different organs and different parts of the same organ in the same individual may show senile changes varying in degree. He styles senility "the final outcome of all the exogenous and endogenous intoxications which have marked the course of the individual's existence." Anglade regards the nerve cell and the neuroglia cell as sisters at war throughout life. Morbid conditions diminish the resisting powers of the nerve cells while they exalt the activity of the neuroglia cell. The former reacts by dying, the latter by proliferating. It is interesting to see how in the end the neuroglia finally triumphs, with the help of all the causes which make for senility. In the decadent brain one element seems endowed with inexhaustible vitality, and this is the neuroglia. Grasset of Montpellier called attention to the preservation of the ability for voluntary movements in patients with cerebral paralysis from sclerosis who drag their feet along the ground, apparently incapable of a better gait, tripping at the least irregularity in the ground. When ordered to lift their thigh up high they find that they can do it easily and well. By taking each joint separately in this way it can be seen that the power of voluntary movement is well retained. The trouble seems to be in the motor automatism, the involuntary mechanism, while the power of voluntary movements is retained to a surprising extent. This distinguishes such cases from those of spinal paraplegia and bilateral cerebral hemiplegia. Meige recommends training such patients in voluntary movements as an effectual means to improve their gait. The discussion of the responsibility of hysterics elicited the usual conflicting views.

LONDON LETTER.

(From Our Regular Correspondent.)

LONDON, Aug. 11, 1906.

Precautions Against the Spread of Diphtheria in Schools.

The London County Council has adopted a recommendation from the education committee to the effect that during the presence of diphtheria in any district the committee should be authorized to refuse to readmit to school children excluded on account of diphtheria or sore throat until they have obtained a medical certificate of freedom from infection based on a bacteriologic examination. This certificate will be accepted either from general practitioners or from health officers.

Industrial Accidents.

The annual report of the chief inspector of factories has just been issued. It shows that 100.609 accidents occurred during the year 1905, of which 1.063 proved fatal. The number of cases of lead poisoning was 592, approximately the same as in the previous year. There were 59 cases of anthrax, an increase of 9 on the previous year. The mortality rate among these was also increased, 16 being fatal, against 10 in 1904. Probably this was due to 7 of the anthrax cases being of the internal variety instead of 1 in the previous year.

Typhoid Fever Due to Shellfish.

Dr. Collingridge, health officer for the City of London, has reported an outbreak of typhoid fever due to cockles. On June 29 he received information of a report of an outbreak of typhoid fever in West Ham. In 52 cases reported 24 of the patients had eaten cockles a short time before the attack. The majority of the cockles were purchased from a dealer at Billingsgate, who had obtained his supplies from Leigh-on-Sea. Between June 28 and 30, six samples of cooked cockles obtained from this source were submitted to Dr. Klein, the city bacteriologist, who examined them to determine whether or not they contained living organisms, which, like the *Bacillus proteus*, *Bacillus coli communis* and streptococci are killed by temperatures of from 154 to 158 F., and whether or not they contained living bacilli of the Gärtner typhoid group. In cultures made from the stomach of the fish, colonies of *Bacillus coli communis* and of streptococci were found in every case, and in two cases also the *Bacillus proteus*. One sample yielded the *Bacillus Gärtner*, or a microbe indistinguishable from it. Dr. Klein concluded that none of the six samples had been sufficiently heated and that they were therefore unsafe. The dealers were at once notified to discontinue the sale of cockles from Leigh-on-Sea, and the fishermen to refrain from sending any more to the market. So long ago as December, 1903, cockles from Leigh-on-Sea were condemned on account of sewage contamination, and it was determined they should be allowed on the market only on the understanding that they were efficiently cooked (raised to a temperature of 212 F. for three and one-half minutes). As it is now found that the fishermen can not be trusted to take this precaution, the corporation of London has absolutely prohibited the sale of cockles from Leigh-on-Sea in the market. As previously reported in The Journal, both cockles and oysters obtained from the estuary of the Thames have given rise to outbreaks of typhoid fever. The whole estuary is polluted with sewage. The facts have been reported to the local government-board in support of the necessity for the long-delayed legislation for dealing with shellfish.

The Official Nomenclature of Disease.

The special committee of the Royal College of Physicians, appointed in 1902 to revise the nomenclature of disease, has presented its report, accompanied by copies of the fourth edition of the "Nomenclature of Diseases." The first edition was published in 1869 under the presidency of Sir Thomas Watson. The book is the standard work of reference authority on all questions of nomenclature, and physicians are directed by the registrar general to follow it in making returns as to the cause of death. The present edition has been ably edited by Dr. J. A. Omerod. The following are some of the most important changes: The enumeration of "Morbid States and Processes," which preceded the general classification of diseases, has been relegated to the appendix, since it is not intended to be used in making returns. The section entitled, "General Diseases," has been divided into four groups: (1) Infective diseases; (2) intoxications; (3) general diseases, not included in the two preceding groups; and (4) certain morbid conditions incident to various parts. In the first group pneumonia appears for the first time; formerly it appeared under local diseases. The true nature of epidemic diarrhea is now emphasized by terming it "infective enteritis." The use of the names, "membranous croup" and "membranous laryngitis" as synonyms for laryngeal diphtheria is forbidden, and the term croup is expunged from the list of diseases. The terms "febricula" and "simple continued fever" are omitted and their place is taken by "pyrexia of uncertain origin." The term "puerperal fever" is expunged. Pyemia, septicemia, or septic intoxication in the puerperium must be described as "puerperal pyemia," "puerperal fever," or "puerperal septic intoxication." Under the last term puerperal sparemia is to be included. The directions as regards vaccination in cases of smallpox are minute. In every case the presence or absence of marks of vaccination and their size, number and character are to be noted. Information is to be given as to whether the patient was (1) unvaccinated; (2) vaccinated in infancy only; (3) vaccinated after infancy; (4) vaccinated only after infection with smallpox; and (5) revaccinated. In returning various forms of tuberculosis the terms strumous and scrofulous are no longer to be used. The third group mentioned above includes anemia, cretinism, diabetes mellitus, exophthalmic goiter, gout, myxedema, purpura, rickets, and scurvy. In the fourth group are included malformations, the effects of parasites, poisons and new growths. In the classification of local diseases the use of names signifying symptoms is discouraged wherever it is possible to trace these to their causes. In particular it is recommended that diseases should be returned under such general causes names as "convulsions," "apoplexy," "paralysis," etc., only when their causes are unknown. When the latter are ascertained the case is to be registered under this head of the primary disease, the secondary affection also being specified. In order to facilitate the correct registration of deaths the usual custom is to forward to every physician free of cost a copy of the work.

Ophthalmological Congress at Oxford.

On July 23, an ophthalmological congress was opened at Oxford; it was organized by Mr. R. W. Doyne, the reader in ophthalmology in the university. Among the foreign guests were Professor Dor, Lyons; Dr. A. Darier, Paris; Dr. Snellen, Utrecht; Dr. A. Antonelli, Paris; Dr. Pergens, Maeyseck; and Dr. Patry, Geneva. Several interesting demonstrations were given. Professor Gotch performed experiments illustrating chromatic aberration of the eye. Dr. Henderson Smith explained the opsonic index. Mr. P. A. Adams showed recent methods of determining the coagulation time of blood in reference to ophthalmic disorders. Mr. M. S. Mayou showed a set of water color drawings illustrative of ocular bacteriology. Mr. J. T. Gradon showed microscopic specimens of several phases of ocular embryology. Dr. Darier demonstrated subconjunctival injections as used by him in the treatment of diseases of the eye. Professor Dor read a paper on "The Treatment of Graves' Disease with Thymus Gland," and Mr. Nettleship one on "Some Hereditary Diseases of the Eye." At the Eye Hospital a demonstration was given chiefly of "Family Diseases of the Eye."

Correspondence

Hay-Fever Treatment by Dunbar's Remedies (Pollantin).

St. Paul, Minn., Aug. 15, 1906.

To the Editor:—In The Journal, August 4, appears a letter from Dr. Ingals, in which he relates his experience with the Dunbar remedies, and an editorial soliciting correspondence on the subject. I have used pollantin to a considerable extent, and find that while benefit is secured in a limited number of cases, it is without result in the large majority. This failure of pollantin to cure cases uniformly is characteristic of all the other so-called remedies for hay fever that have been tried for decades. It certainly suggests that the empirical search for a specific should be abandoned in favor of investigation into the nature and location of the disease. May there not be some good reason for the failure of pollantin and other remedies in that they have failed to reach the real seat of the trouble? May not the success of the remedy in a few cases be due to the fact that it has by accident, rather than design, penetrated to the structures that are involved in the production of hay fever?

During the past three years I have devoted myself to investigation of the antrum of Highmore, and my experience warrants me in the statement that hay fever is of organic origin, with a basic lesion situated in the antra, and I believe that any treatment which is not directed to removing the inflammation of those cavities will fail to cure hay fever. Treatment of the antra for hay fever has been uniformly successful at my hands. Treatment of the antra in unmistakable hay fever has controlled the seizures in three or six days, and in those cases in which asthma was present, it disappeared simultaneously with the other symptoms. The findings following irrigation of the antrum with a boric-acid solution are: First, a secretion resembling buttermilk, with particles of white curdy substance; second, a serous fluid tinged with milk color. The disappearance of this secretion is followed by complete relief of the symptoms of hay fever, together with those of neurasthenia and asthma. The relation of this secretion to hay fever is demonstrated by the fact that it is not found in the antra of normal persons. This secretion is produced by a secretory inflammation induced in the antrum by the entrance of pollen, dust and other exciting causes of hay fever. My experience teaches me that those suffering from hay fever have a much larger ostium than normal persons, thus favoring the entrance of pollen and other substances. May we not explain the presence of hay fever in some and its absence in others by the varying size of the maxillary ostium? It is impossible in the limits of a letter to do more than to hint at the nature, locus morbi and treatment of the disease, but in a report now in preparation the pathologic, anatomic and therapeutic facts of antral disease will be presented. The object of this communication is solely to endeavor to explain why pollantin and other so-called remedies fail to cure the distressing conditions, and to suggest that we have heretofore been directing our efforts to the wrong anatomic structures.

Jacob E. Schadle.

LeMars, Iowa, Aug. 17, 1906.

To the Editor:—I have been very much interested in the recital of the various physicians' experiences in the use of pollantin. This is the third season I have used the serum in treating my hay-fever patients, and my experience with it has been very gratifying. I do not recall a single patient that has not been benefited by its use, and some have told me that they have enjoyed comparative freedom from attacks by using the serum and powder fairly regularly throughout the season. I very much deprecate the container used for the medicine. It is a great nuisance for the physician to be obliged to remove all the advertising matter, etc., before dispensing the serum. Can not these people be induced to put the medicine out in some other form? It seems to me that those containers were made especially for display on the drug-store counter. Some time since I had some correspondence with Fritchie Brothers on this very point, and it was, to say the least, amusing to read their very lame explanations of the reasons for so doing.

F. S. Clarke.

The Report of the Council on Medical Education.

To the Editor:—The recent report of the Council on Medical Education in The Journal A. M. A., June 16, 1906, page 1853, invites comment and suggestion. I am prompted to indulge in such comment because it seems to me that in this present time, full of great possibilities for advancement in medical education and practice, nothing will promote sure and rapid progress, and the avoidance of missteps, more certainly than a full and free discussion by all who are in any way related to, or interested in, the subject.

The decision of the Council to make its chief function that of co-ordinating the various forces at work among them, the medical schools and their associations, the literary colleges and medical examining boards, can not be too highly commended. It would have been a great mistake at this time to have attempted to force any arbitrary standards by drastic measures, such as the requirement that no physician, who failed to comply with certain standards, should be eligible for membership in the American Medical Association or in any of its constituent bodies. In this growing period of the Association the supreme effort should be to strengthen itself numerically by seeking the allegiance of every physician who is at all worthy of membership, and any action which would interfere with this movement would be unwise. In later years more radical measures and rigid standards may be indicated and may be possible of enforcement.

Most commendable also is the decision of the Council to carry on the work inaugurated by The Journal some years ago of gathering information in reference to the medical schools, the medical practice acts and state board rulings, and of the results of the examinations for licensure in the several states, etc. It seems to me, however, that in reference to the statistics of the examinations for licensure the fact should be again emphasized that these statistics must not be interpreted too literally, nor can the results be accepted as furnishing an accurate criterion of the relative merit of the several colleges. No one who is at all familiar with the character and the work of these schools can fail to discover that their relative rank, as they appear in the tables presented by the Council, bears little relation to their relative actual merit as teaching institutions. Some of the schools listed in the second group (showing from 10 to 20 per cent. of failures) or even the third group (over 20 per cent. of failures), are certainly not inferior to some of those which appear in Group I (having less than 10 per cent. of failures).

The reason for this is to be found in the wide discrepancy between the character of the examinations by the state boards—purely written tests as they are, almost without exception—and the practical, objective methods of teaching in vogue in the better medical colleges. For a quarter of a century now there has been a gradual and steadily growing departure fro the purely didactic and "cram" methods of instruction toward the methods which develop in the student the power to see, to hear, to feel, to do and to think, by the actual exercise of his faculties in the laboratory, the practical course and the clinic. While this movement has been going on, the character of the examinations has changed not at all, and they are at present so far removed from the modern methods of education as to afford an entirely inadequate and unfair test of the student's accomplishments or of his ability to practice his profession. It is difficult to understand why the examining boards have been so slow to realize this fact when one remembers that really effective and rational methods of examination for licensure have been practiced in all foreign countries for many years. Possibly the explanation is partly to be found in the personnel of the examining boards, which have been so largely composed of men with no experience or training as teachers or examiners. Certainly, it seems to me, that so long as the state board examinations are conducted on lines so antiquated and so foreign to the modern methods of education in the high-grade medical schools, just so long will the results of these examinations be no fair criterion of the merits of these schools or of their graduates.

The most important items of the report of the Council are the recommendations: 1, For an ideal standard of requirements, and 2, for a fixed, uniform medical curriculum. The ideal standard proposed by the committee comprises six years of study between graduation from a four-year high school and the reception of the degree of M.D. This arrangement proposes the addition of one year antecedent to one year subsequent to the present four-year medical curriculum, the antecedent year to be devoted to physics, chemistry, biology and German in preparation for the purely medical studies, while the closing year shall consist of practical work in a hospital or dispensary.

Few medical educators will dissent from the opinion that the time has come when a longer period than is now required must be given to preparation for the practice of medicine. The year of practical hospital training, already instituted by at least one American college, is of the utmost value, but not so indispensable as the provision for a more adequate preliminary training. Opinions will differ as to the sufficiency of one year of preparatory work beyond the high school, as requirement is already exacted in some colleges of two, three or four years, but all will welcome the addition of even one year of such work, provided, however, that it be done under such conditions and by such men as to insure its efficiency. And this is the point on which I wish to comment. To my mind the Council has made a grievous mistake in specifying that this preparatory year *may* be done in the medical school, or in a literary or scientific college. The failure to insist that these branches of general learning (for such physics, chemistry, biology and German surely are), must be taken in a college or university, where alone, with very rare exceptions in this country, they are properly taught, results in making this recommendation of the Council a step backward rather than forward, because it will tend still further to defer tha time, which I think we all realize should be the goal of ou desires, when every medical graduate will be a broadly cu tured, a college-bred man. What will be the actual working of this scheme to permit the medical school to add another year to its curriculum, and to exact another annual tuition fee from its students, may easily be foreseen by all who know the history of similar attempts of medical schools in former years to give instruction in non-medical branches. It is true that in Germany the gymnasium graduate enters the medical school with little or no scientific training—or did so until recently, but it is to be remembered that the situation in that country is wholly different from our own, for every medical school is an intimate and integral part of a university and the instruction in physics, chemistry and biology is in the hands of the university professors of these branches. The more strictly our own medical—purely professional—schools, devote themselves to the teaching of the purely medical branches, and the more completely they rely on institutions of general learning to do the preparatory work which belongs to them, the better will be the results secured. We may be sure that if the order for this preparatory year is promulgated by the examining boards as it is recommended by the Council, the very first institutions in the field with a blatant advertisement of their superior facilities for giving such instruction will be the most poorly equipped medical colleges, and those of the lowest standards. So far from operating to suppress the cheaper schools, the extinction of which is so greatly to be desired, the effect will be to give them an additional hold on their students and to enable them to secure fees for another year of relatively inexpensive instruction. It is very much to be hoped that before the action of the National Confederation of Examining Boards requiring this preparatory year goes into effect in 1910, it will be so amended as to specify that this work must be taken in a literary or scientific college. It is hard to understand why there should be so much eagerness on the part of some to eliminate the literary and scientific schools from our scheme of medical education. The medical schools and the medical profession need their coöperation quite as much as they need our support, and no ideal scheme of medical education can be constructed in this country which fails to include them as an integral part of the system. It is true that there are poor and spurious colleges, as there are cheap medical schools, though the proportion is not so large, but these can be easily discovered and designated. The council should reckon as one of its most important functions such an investigation and classification of the literary and scientific colleges.

I had intended to comment on the so-called ideal curriculum which has been proposed by the council, as well as on other fixed curricula which have been laid down, among them that of the Michigan State Board, and of the Association of American Medical Colleges, but I have already trespassed too much on your space for one communication and must reserve this item for a later discussion. John M. Dodson.

Wants to Arrest "Patent Medicine" Man.

Albion, Mich., Aug. 20, 1906.

To the Editor:—I want information of one W. Thompson, "the oil man." He was arrested here for practicing medicine without a license, gave bail for appearance at hearing, and did not appear. He has since been in Ypsilanti, Mich., and Findlay, Ohio, and was last heard from in Windsor, Ont. He travels with four comedians, sells from a wagon, and is a very smooth talker, of dark complexion, straight black hair, rather below medium height, about 40 years of age. He sells a soap, a blood medicine, and "Egyptian Oilio" (which is said to be colored gasoline), claims to represent a quarter-million dollar company, and has five diplomas. The sheriff is prepared to get him anywhere in the United States. If some physician who believes in protecting the public from swindling impostors will wire me on his appearance in any town we will be duly grateful and do the rest. George C. Hafford.

A Yellow Peril.—Under this head J. W. Croskey, in the *Medico-Chirurgical Journal*, May 20, includes trachoma which he says is more prevalent in Japan than in any other country, although it is also common in India and Egypt. In all these countries its spread is favored by religious observances and superstitions such as ablutions with use of a common towel. The danger is shown by the fact that the proportion of trachoma cases in immigrants at eastern ports is less than one in 1,000, while at western ports it rises to nearly one in 60. Greater care in examination of immigrants and more stringent measures to prevent the spread of this disease are needed.

Miscellany

Effect of Alkalies and Other Drugs on the Efficiency of Pepsin.—While the therapeutic inefficiency of pepsin without the simultaneous presence of an acid, preferably hydrochloric acid, has been emphatically stated often enough so that it should be thoroughly understood, this ferment is still frequently prescribed in mixtures containing no acid and in combination with substances which destroy the enzyme, so as to defeat the purpose for which it was intended. Many neutral salts, alkaloidal and other substances have been shown to have a retarding influence on the action of pepsin, while digestion with strong alkali destroys the enzyme altogether. J. F. Tocher has investigated the action of dilute alkalin solutions, as well as that of morphin and bismuth, substances which are often prescribed in mixtures with pepsin. He gives the following conclusions: 1. Solutions of sodium bicarbonate, sodium, potassium and ammonium hydrates when added to solutions of pepsin in the cold have an immediate inhibitory or destructive influence on pepsin, according to the concentration. In ordinary concentrations the effect is to destroy the enzyme immediately. 2. Dilute solutions of caustic alkali immediately destroy the activity of dilute solutions of pepsin. One millimeter (1 c.c.) of decinormal ammonia (0.0017 gm., NH_3) is sufficient to destroy the proteolytic power of 5 mgr. of pepsin in 5 mm. (5 c.c.) of water. That is, a 0.1 per cent. solution of pepsin with an alkalinity equal to 0.017 per cent. has no proteolytic power whatever. On acidifying and digesting, the enzyme is found to be destroyed. Pepsin should, therefore, never be prescribed with alkalies. 3. Carbonate of bismuth precipitates pepsin from aqueous solutions; subnitrate of bismuth does not. 4. Compound mixtures containing solution of bismuth, morphin, carmin, etc., should contain no pepsin, since the activity of the enzyme is much retarded by the morphin and is destroyed proportionately to the amount of alkali present in solution.

Ethyl Chlorid.—J. H. Chaldecott, in the *Clinical Journal* for August, discusses the uses and abuses of this comparatively new anesthetic. It is interesting and somewhat instructive to note that the adoption of this anesthetic in England owes much of its progress to the advertisement of somnoform and that some of the abuses of the drug have been due to the misleading and unduly favorable reports sent out by these manufacturers. Chaldecott, after extensive use of ethyl chlorid, adheres in the main to the conclusions which he published in 1904: 1. It is the best anesthetic known for single-dose cases, viz., those in which anesthesia is induced, the mask removed and the operation performed without any further administration. The statement still holds good for children, but in adults he prefers the nitrous oxid and ethyl chlorid mixture, which he regards as an ideal anesthetic in cases requiring an available anesthesia of from forty seconds to two minutes. 2. It is certainly worthy of an extensive trial in all minor operations. He does not see any advantage in ethyl chlorid after the first few minutes of anesthesia, it being more difficult to secure an even degree of narcosis than with ether or chloroform, and the after-effects of continued administration being practically identical with those of chloroform. 3. It is a safe and rapid means of inducing anesthesia as a preliminary to chloroform. This conclusion must be modified in the light of recent fatalities from the drug, and the ethyl chlorid ether sequence should be substituted for the gas-ether sequence only under circumstances which contraindicate the use of nitrous oxid. 4. Although its effects are transient, it is doubtless a powerful anesthetic and should be carefully administered and the patient properly prepared. The following objections to this anesthetic have been raised and are considered by Chaldecott: 1. Uncertainty of action. This has generally been due to the administration with too much air. 2. Rigidity. This has not been true in the author's experience. 3. After-effects. These have largely been due to imprudent use, and when the drug is properly administered they are very slight. 4. Danger to life. It must be admitted that although the proportion of fatal results is infinitesimal compared with the number of actual administrations, the drug offers an appreciable mortality and this fact ought to discourage its haphazard administration by dentists who are not qualified medical men and who have had no training in administration of anesthetics.

Influence of Pregnancy on Deafness.—Pregnancy, according to W. Milligan, in the *Journal of Laryngology, Rhinology and Otology* for June, may be the occasion of deafness due to vasomotor disturbances, which are transient, passing away after the termination of the pregnancy, or it may cause progressive changes due to the aggravation of pre-existing septic processes in the ear, which extend to the nerves of hearing in consequence of the diminished resistance produced by the toxemia of pregnancy. Simple catarrhal troubles may also be so aggravated that the deafness becomes more pronounced. These changes occurring in successive pregnancies present an unfavorable prognosis, since treatment, either local or general, seems to exercise little influence in retarding the advance of the disease. In consideration of these facts Milligan raises the following queries: (1) The advisability or otherwise of young women already the victims of advanced chronic middle-ear catarrh, purulent or non-purulent, or of otosclerosis, entering into matrimony; (2) if marriage has already taken place and the existing deafness has been materially increased by a first pregnancy, the advisability or otherwise of suggesting means to prevent any further pregnancy, and (3) if in a case of advanced deafness, where previous pregnancies have invariably increased the existing deafness, whether it is advisable or justifiable to induce premature labor. [Premature labor at the seventh to eighth month might be permissible in aggravated cases, but under no circumstances should an abortion necessitating the death of the fetus be considered justifiable for an affection entailing only inconvenience and no serious danger to the life of the mother.—Ed.]

An African Cure for Sleeping Sickness.—In a letter to the editor of the *Journal of the Royal Army Medical Corps*, Major Smith, R.A.M.C., states that eight years ago, while serving in the Sherbro and Mendi country in Sierra Leone, he noticed many people with scarred necks, and on making inquiry he was told that the glands had been removed by native doctors to prevent or to cure sleeping sickness. The natives informed him that at one time sleeping sickness had been rather frequent in the neighborhood, but that after the people found that removal of the "nuts" or "banga" was efficacious the disease had become rare. Whether the removal of the glands in the earlier stages of the malady could be of service in treatment it is impossible to say, but scientific medicine, Major Smith states, has confirmed the native opinion that enlargement of the glands is an early symptom. He offered about 50 cents a head for the names and whereabouts of patients with sleeping sickness, but was unable to find one till 1901. The man was a creole-negro who had been to the Congo two years previously. Subsequently Major Smith saw two or three cases of sleeping sickness in the colony, but all had a history of having been to Fernando Po, Congo, or elsewhere down the coast. The last case he saw was under Dr. W. Renner in the Colonial Hospital in 1904, and from this he successfully inoculated the common "mango monkey" and a rat with blood which had been for two hours or so in diluting fluid.

Gold Wire for Sutures in Hernia.—Siegmund Arkel, Milan (*Medicinische Klinik*, March 18, 1906), calls attention to the use of gold wire for sutures in hernia operations as practiced by Tansini of Pavia. The comparative antiseptic action of gold is shown by a series of experiments *in vitro* and on rabbits by Vecchi (*Il Morgagni*, Nos. 7 and 8, 1905) of which Arkel gives an abstract. Tansini has used this material in 360 hernia operations without a single case of early or late suppuration, and the patients were able to leave the bed by the seventh day. Like results were obtained by Professor Titone at Palermo in 25 cases, and by the surgeons Crosti and Rossi in the general hospital of Milan, in 14 and 40 operations, respectively, in the same rooms and under the same conditions as operations in which silk or catgut had been used and followed by infection. The cost of the gold sutures is not prohibitive, as 50 cm. of the suture weighed only 12 centigrams, and 120 centigrams of gold only costs five lire (about 95 cents). The slightly greater cost over silk or catgut is not worth considering when one takes into account the durability and the lessened danger of infection from handling, etc.

Marriages

Frank M. Hagans, M.D., to Miss Maud Mangas, both of Lincoln, Ill., recently.

James A. McCracken, M.D., to Miss Mary Snyder, both of Kane, Pa., August 8.

John R. Murnan, M.D., to Miss Edith Kercheval, both of Covington, Ky., August 14.

Francis J. Jones, M.D., Providence, R. I., to Miss Alice M. Kelley of Boston, August 8.

V. D. Farmer, M.D., Parma, Mich., to Miss Grace Dutcher of Jackson, Mich., August 14.

Patrick J. Sullivan, M.D., to Miss Malvina Moran, both of Muskegon, Mich., August 8.

Joseph W. Jauch, M.D., to Mrs. Mary A. Hotchkiss, both of Los Angeles, Cal., August 7.

Kimsey C. Evans, M.D., Edgerton, Ind., to Miss Nellie Brady of Fort Wayne, Ind., August 4.

W. Frank Bell, M.D., Plain Dealing, La., to Miss Maude Mosby, at Easton, Md., August 8.

Stanley Castle, M.D., Springfield, Ill., to Miss Elsie Mary McDowell of Chicago, August 14.

James Christianson, M.D., Alden, Minn., to Miss Maud Brackney, at Washta, Iowa, August 15.

Norman Charles Bledsoe, M.D., Bisbee, Ariz., to Miss Marriet Gage of Los Angeles, Cal., August 9.

William H. Taylor, M.D., Philadelphia, to Miss Anna Evalynn Bullock of New York City, August 1.

Charles D. Wall, M.D., Chicago, to Miss Jessie D. Boone of Nashotah, Wis., at Davenport, Iowa, July 18.

John A. English Eyster, M.D., Baltimore, to Miss Mary Elizabeth Adams, at Middleburg, Va., August 8.

Harold W. Baker, M.D., Worthington, Minn., to Mrs. Maxwell Stevenson of New York City, in Worthington recently.

Deaths

James Brown McCaw, M.D. New York University, New York City, 1844; said to have been oldest physician of Richmond, Va.; professor of chemistry in the Medical College of Virginia, 1865, and later professor of practice of medicine, and for twelve years dean of the college and, at the time of his death, chairman of the board of visitors of the institution; a surgeon in the Confederate service during the Civil War, and in charge of the Chimbarazo Hospital, Richmond, in which were treated more than 76,000 patients during the war; editor of the *Virginia Medical Journal* from 1853 to 1861 and of the *Confederate States Medical and Surgical Journal* from 1864 to 1865; a charter member, one of the founders, and some time president of the Medical Society of Virginia, and some time president of the Academy of Medicine and Surgery, Richmond; president of the Richmond Eye and Ear Infirmary; who on his retirement from practice in 1901 was tendered a banquet at which he was presented with a handsome silver loving cup, died at the home of his son-in-law in Richmond, August 13, from senile debility, aged 83. Of six surviving children, two sons, Dr. David McCaw of Richmond and Major Walter D. McCaw, surgeon, U. S. Army (at present librarian and officer in charge of the library of the Surgeon-General's office, having succeeded the late Major Walter Reed in this position in 1903), are members of the medical profession representing the fifth generation of a remarkable line of Virginia physicians.

Charles Stockton Gauntt, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1844; the oldest alumnus of the University of Pennsylvania; after graduation a professor at Girard College; later he became a member of the faculty of the Jefferson Medical College; a surgeon during the Civil War, and connected at different times with many institutions as medical instructor, died at his home in Philadelphia, August 16, aged 83 years.

Daniel S. Ellis, M.D. College of Physicians and Surgeons, Baltimore, 1870; a member of the Medical Society of Virginia, and surgeon to the Randolph-Macon College, Ashland, Vt., was drowned while crossing a swollen creek near home in Ashland, Ill., in answer to a professional call, August 12, aged 52.

Charles Edwin Jakeway, M.D. Toronto University Medical Faculty, 1871; died from asphyxiation at his home in Stanaer, Ont., March 1. While getting hay for his horse at night his lantern exploded, igniting the hay and straw in the loft and smothering him.

J. W. Ferguson, M.D. University of Louisville, Medical Department, 1889; a member of the American Medical Association, and a well-known practitioner of Bourbon County, Ky., died at his home near Shawham, August 9, from malignant disease, aged 49.

W. A. Goode, M.D. Atlanta (Ga.) Medical College, 1890; a member of the North Carolina Legislature, in 1903, from Cleveland County, died at his home in Shelby, N. C., August 3, after an illness of several weeks, from typhoid fever and nephritis.

Charles Albert Cochrane, M.D. Medical School of Maine at Bowdoin College, Brunswick 1856; a member of the Maine Medical Association, died at his home in Winthrop, Maine, from angina pectoris, after an illness of a month, aged 73.

John Onins Pierce, M.D. Pennsylvania University of Medicine and Surgery, Philadelphia, 1870; a veteran of the Civil War, died at his home in Milford, Del., July 11, from paresis, after an illness of more than twelve years, aged 63.

William E. Chamberlin, M.D. Charity Hospital Medical College, Cleveland, 1870; a veteran of the Civil War, died at his home in Akron, Ohio, August 11, from cerebral hemorrhage, after an illness of seven weeks, aged 65.

Felix Maslowsky, M.D. Hospital Medical College Louisville, 1875; a member of the Spencer County (Ind.) Medical Society, died at his home in Mariah Hill, April 6, from dropsy, after an illness of two months, aged 61.

Melville B. Estes, M.D. University of California Medical Department, San Francisco, 1888; died at his home in Vallejo, July 9, from lung disease, aggravated by shock due to the San Francisco earthquake, aged 47.

Samuel Ramsey, M.D. Cleveland Medical College, 1846; a veteran of the Mexican War, died at his home in Seattle, Wash., May 12, from senile debility, after an invalidism of four years, aged 81.

Charles Tylden Whaland, M.D. Maryland Medical College, Baltimore, 1905; of Chestertown, Md., died in the Maryland General Hospital, Baltimore, August 14, from spinal meningitis, aged 22.

William H. Davis, M.D. Medical Department of Washington University, St. Louis, 1878; of Bethany, Ill., president of the school board of that town, died in St. Louis, Mo., August 3, aged 51.

Jerome W. Flanders, M.D. Miami Medical College, Cincinnati, 1868; a member of the Jefferson County Council, died suddenly at his home in Dupont, Ind., from heart disease, August 11, aged 59.

William Jacoby, M.D. Medical Department of Western Reserve University, Cleveland, 1868; of Vernon Center, Minn., died May 31, in St. Joseph's Hospital, Mankato, Minn., aged 88.

Robert Joseph Brevard, M.D. New York University, New York City, 1872; twice mayor of Charlotte, died at his home in Charlotte, N. C., after an illness of several weeks, aged 57.

James Brown Combs, M.D. Medical College, Cincinnati, 1851; died at the home of his daughter in Washington, Iowa, recently, after a short illness, from cerebral hemorrhage, aged 81.

Lorenzo D. Bartlett, M.D. Castleton (Vt.) Medical College, 1862; died at his home in Keokuk, Iowa, August 14, from cerebral hemorrhage, after an illness of four days, aged 81.

Howard Graham Wetmore, M.D. College of Physicians and Surgeons in the City of New York, 1879; died at his home in High View, N. Y., April 27.

William H. Kesla, M.D. College of Physicians and Surgeons, Baltimore, 1896; died at his home in Austin, Pa., in June, from tuberculosis, aged about 35.

Lot S. Pennington, M.D. New York, 1837; died at his home in Sterling, Ill., July 31, from senile debility, after an illness of five years, aged 93.

Albert S. Hazard, M.D. State University of Iowa, College of Medicine, Iowa City, 1888; died at his home in La Vita, Colo., June 12.

Alma L. Rowe, M.D. Northwestern University Women's Medical School, Chicago, 1893; died at her home in Forest, Miss., May 27.

R. L. Cooper, M.D. Jefferson Medical College, Philadelphia, 1852; died at his home in Shelbina, Mo., August 3, aged 80.

David L. Delk, M.D. Chattanooga (Tenn.) Medical College, 1897; died at his home in Oakdale, Tenn., August 12.

DEATH ABROAD.

A. Vincent, M.D., professor of hygiene and president of the cantonal board of health, died at Geneva, July 23. He recently served as vice-president of the international conference for revision of the Geneva Convention.

THE PHYSICIAN'S LIBRARY AND THE FILING OF CLIPPINGS FROM JOURNALS.

Seneca, N. C., July 23, 1906.

To the Editor:—The editorial in The Journal, June 2, 1906, page 1698, regarding the use of our public libraries by physicians remote from the centers of medical education was timely and worthy of more than passing notice. I believe, however, that you can render the rank and file of the profession an equal service by suggesting the methods of greatest value in searching out and using the material we have at our own door— for instance, suggestions as to purchasing the best books and building one's own library. Again, if you could help the average physician to grasp a tithe of the knowledge which comes almost daily to his desk in the periodicals of more or less value you would render him a service. It is impossible to have all these numerous journals bound as a public library may do, and yet it is often necessary to refer to them. I have found that the average physician has no system whatever to aid him in quickly referring to a journal article a few months or a few years old. If you, or any one else, can furnish a tried and true method for a busy practitioner you will earn his lasting gratitude.

E. A. Hines.

Answer.—The standard text-books are landmarks, so to speak, of the state of medical science at the time of their publication. Unfortunately, however, in many departments of medicine they change too rapidly in successive editions, and the up-to-date physician, if he depends on them, is subjected to considerable expense in purchasing the latest and best revised editions. It is only through medical journals that one can keep accurately in step with the progressive science of medicine, and a file of one or two of the leading weeklies, containing, as they nowadays do, not only original articles summarizing the facts known on their subjects, but also abstracts and summaries of the current medical literature of the day, and all elaborately indexed for each volume, is almost indispensable in the physician's library. One can not, however, preserve all the periodical literature that comes to hand, though much of it is certainly deserving of preservation. In the numerous sample copies that every physician receives, there are often articles that he would like to have on hand for ready reference, and the best way for systematically preserving these is a classified series of clipping envelopes which can be improvised at a minimum of expense and very little trouble by any systematic man. If in addition to the clippings, a card index of articles and subjects in which one takes a special interest is kept, even if only on scratch-paper pads, little more will be required. We have known of elaborate papers, reasonably exhaustive in literary references, being prepared from just such memoranda, and there are probably many such. Of course, one can not trust to second-hand references in any really valuable work, though more of that is done than is often admitted, in Europe as well as in this country, as Virchow once pointed out. Such a card index, giving brief statements of the substance and points of interest in the articles referred to, will often be found very convenient. It is much better than trying to keep a commonplace book of the old style, as it is much more easily made without regard to time or place of working, and the cards or slips can be kept in any convenient drawer or box, or perhaps, as well, like the clippings, in labeled envelopes. Such notes can also be made at society meetings, and in libraries where pencil references are generally allowed, on the uniform size scratch-pads and filed away later with very little trouble. We believe that a simple system like this will be found as practical as any other and equally advantageous. We might add a word as to the usefulness of journal clubs. If several physicians residing near each other coöperate, each taking certain journals not subscribed for by the others, and exchanging among themselves, each keeping and binding those for which he subscribes, a considerable widening of the field of reading and note-taking can be accomplished.

MICROSCOPES.

NEAL, KAN., Aug. 11, 1906.

To the Editor:—Can you recommend any make of microscope that is not too expensive and yet which can be relied on for histology and bacteriology work? Are American microscopes as good as foreign?

B. L. HALE, M.D.

ANSWER.—American microscopes—Bausch & Lomb and Spencer—are as good as the more common foreign makes, among which the Leitz microscope is probably most widely used in this country. Bausch & Lomb *sell microscopes in Europe*, especially France. The best microscope, and also the most expensive, is the Zeiss, which is in great favor with investigators. Any one of the following microscopes will answer fully for the practitioner: Zeiss, Bausch & Lomb, Leitz, Spencer, Reichert. With ordinary care and in a temperate climate a new microscope of any of these makes should last at the very least twenty-five years with only minor repairs. If bought from a reliable agent, so that no fraud of any kind is practiced, which is very rarely possible, such a microscope can be relied on absolutely for histologic and bacteriologic work, provided, *of course, that an adequate equipment of objectives* is included. Three objectives and two eye-pieces with substage condensers and diaphragm are requisite for satisfactory work in clinical microscopy. Without the oil immersion objective many bacteria are seen only with difficulty, and two dry objectives, one low and one high power, are essential. The Bausch & Lomb microscope BBa is gotten up especially for the practitioner and has the lenses, etc. mentioned. It sells for $75.00 net. Leitz and Spencer have similar instruments, the Spencer at the same price, we believe, as the Bausch & Lomb, the Leitz being a little higher. The Zeiss comes at least 50 per cent. higher. We have given details so freely because the microscope is probably the most expensive single instrument that the practitioner must have and use in order to do himself and his patients justice, and some physicians in starting out may possibly postpone purchasing the microscope because of the impression that it is more expensive and more risky to buy than really is the case. To the modern progressive physician the microscope is as necessary as the stethoscope—and many think they must have various accessories that run into money, but while these may be advantageous, they are not absolutely necessary to enable one to do ordinary clinical work.

DOSAGE FOR INFANTS.

NEAL, KAN., Aug. 13, 1906.

To the Editor:—I notice that in THE JOURNAL, Aug. 11, page 456, some one asks about dosage for infants under one year. My rule is this: Ascertain the weight of the baby and taking 150 pounds as the average weight of an adult, use the child's weight for the numerator and an average adult's weight for the denominator, thus: child's weight, 15 pounds; adult, 150; we have 15/150 = 1/10 *of an adult dose.*

B. L. HALE.

MCCAMMON, IDAHO, Aug. 16, 1906.

To the Editor:—In all scientific works on animals the weight of the animal is considered in connection with the dose. I believe in following the same rule in regard to human beings. It is not natural to suppose a man weighing 95 pounds should be given the same dose as one who weighs twice as much; or a large strong child should be given the same dose as a small one, even though they be the same age. Yet this is frequently done when a dose is figured according to Young's rule. I usually consider that the medium dose of a drug is intended for an adult weighing 150 pounds and vary according to the percentage of that weight. Of course one must consider whether a slight or a strong action is required, and must remember the varying effects of certain drugs on children.

J. W. ROBINSON, M.D.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, for the week ending August 18, 1906:

Appel, D. M., deputy surgeon-general, detailed for duty as member of examining board for promotion or advancement of medical officers, Army General Hospital, Presidio of San Francisco, Cal., during the temporary absence of Lieut.-Col. George H. Torney, deputy-surgeon-general.

Reed, Howard A., asst.-surgeon, relieved from temporary duty in the Department of California, and will report at once to medical superintendent, Army Transport Service, San Francisco, Cal., for duty on the transport *Logan*.

Smith, Lloyd L., asst. surgeon, relieved from duty as surgeon, U. S. A., transport *Logan*, and ordered to West Point, N. Y., for duty.

Banister, J. M., deputy-surgeon-general, left Fort Riley, Kans., on 30 days sick leave of absence.

Clayton, J. B., asst.-surgeon, arrived at Camp of Instruction, Fort Riley, Kans.

Usher, F. M. C., asst.-surgeon, left Fort Brady, Mich., en route to Camp of *Instruction, Fort Benjamin Harrison*, Ind.

Woodson, R. S., surgeon, left Fort McDowell, Cal., en route to Camp of Instruction, American Lake, Wash.

Purnell, H. S., asst.-surgeon, left Camp of Instruction, Islay, Wyo., on leave of absence for 30 days.

Kirby-Smith, R. M., asst.-surgeon, upon arrival at San Francisco, Cal., will report for duty at the Army General Hospital, Presidio of San Francisco, Cal.

Woodall, William P., asst.-surgeon, relieved from duty at Army General Hospital, San Francisco, Cal., and ordered to Camp Mabry, Tex., for duty. Upon the abandoment of Camp Mabry to proceed to Fort Clark, Tex., for duty.

Miller, E. W., asst.-surgeon, relieved from duty at Camp Mabry, Austin, Tex., and from duty at Fort Clark, Tex., *and ordered to* Fort Riley, Kans., for duty.

O'Connor, R. P., asst.-surgeon, relieved from duty at Army General Hospital, Presidio of San Francisco, Cal., and ordered to Fort Leavenworth, Kans., for duty.

Buck, Carroll D., asst.-surgeon, relieved from duty at Fort Leavenworth, Kans., and ordered to the Army General Hospital, Presidio, San Francisco, Cal., for duty.

Stedman, C. J., asst.-surgeon, upon arrival at Seattle, Wash., will proceed to Camp of Instruction, American Lake, Wash., for duty. Upon abandonment of camp, ordered to Fort Stevens, Ore., for duty.

Connor, C. H., asst.-surgeon, relieved from duty at Fort Stevens, Ore., and ordered to the Army General Hospital, Presidio, San Francisco, Cal., for duty.

Hall, James F., asst.-surgeon, relieved from duty at Army General Hospital, Presidio, San Francisco, Cal., and ordered to Fort Flagler, Wash., for duty.

Persons, E. E., asst.-surgeon, relieved from duty at Fort Flagler Wash., and ordered to take first available transport sailing from San Francisco, Cal., to Manila, and upon arrival at the last named place to report in person to the commanding general, Philippines Division, for assignment to duty.

Bosley, John R., asst.-surgeon, upon arrival at Seattle, Wash., will proceed to Jefferson Barracks, Mo., for station and duty.

Lewis, W. F., asst.-surgeon, so much of par. 22, S. O. 282, War Department, Dec. 5, 1905, as details him for examiner of recruits is revoked.

Scott, George H., asst.-surgeon, now on leave at Denver, Colo., will proceed to Camp of Instruction, at the target and maneuver reservation, near Fort D. A. Russell, Wyo., for duty. Upon completion of which he will return to Denver, Colo. and resume his leave.

Murtagh, John A., asst.-surgeon, detail as examiner of recruits, San Francisco, Cal., is revoked.

Hartsock, F. M., asst.-surgeon, detail as examiner of recruits, New York City, is revoked.

Jones, Percy L., asst.-surgeon, detail as examiner of recruits, Portland, Me., is revoked.

Truby, Willard F., asst.-surgeon, left Fort Niagara, N. Y., with 3d Batt., 12th Inf., en route to Mount Gretna, Pa., for duty at Camp of Instruction.

Brechemin, Louis Jr., asst.-surgeon, arrived at Camp Tacoma, Murray, Wash., for duty.

Davidson, W. T., asst.-surgeon, arrived at Camp Tacoma, Murray, Wash., for duty.

Ireland, M. W., surgeon, left Washington, D. C., en route to the Army General Hospital, Presidio of San Francisco, Cal., on temporary duty.

Bartlett, C. J., asst.-surgeon, arrived at Camp Tacoma, American Lake, Wash., for duty.

Devereux, J. R., asst.-surgeon, relieved from duty at Fort Logan, Colo., and ordered to Army General Hospital, Washington Barracks, Washington, D. C., for duty.

Koerper, C. E., asst.-surgeon, relieved from duty at Army General Hospital, Washington Barracks, Washington, D. C., and ordered to Fort D. A. Russell, Wyo., for duty.

Howard, Deane C., asst.-surgeon, granted 20 days leave of absence.

Smith, Lloyd L., asst.-surgeon, granted 5 days leave of absence.

Kelly, John P., contract surgeon, reports arrival at Fort Miley, Cal., for temporary duty.

Chase, A. M., contract surgeon, reports at Camp of Instruction, Austin, Tex., for duty.

Tuttle, George B., contract surgeon, returned to Fort Columbia, Wash., from leave of absence.

Slayter, John T. H., contract surgeon, relieved from duty in the Philippines Division, *to take effect about Oct. 10, 1906, and upon* arrival at San Francisco, Cal., to report to the Military Secretary of the Army, for further orders.

Hammond, William G., dental surgeon, reports arrival at Fort Logan, Colo., for duty.

Richardson, George H., contract surgeon, when his services are no longer required on transport *Buford, ordered to proceed* to San Francisco, Cal., and report in person to the commanding general, Department of California, for assignment to duty.

Jenkins, Frederic E., contract surgeon, *ordered to proceed* from Hancock, Md., to San Francisco, Cal., and take transport to sail from the latter place on or about Sept. 5, 1906, for the Philippine Islands, and upon arrival at *Manila to report in person* to commanding general, Philippines Division, for assignment to duty.

Davis, Oscar F., contract surgeon, granted leave of absence for three months, to take effect upon being relieved from duty at Fort Des Moines, Iowa.

Reagles, James, contract surgeon, reports his arrival at Fort Keogh, Mont.

Miller, William G., contract surgeon, upon arrival at San Francisco, Cal., ordered to proceed to Fort D. A. Russell, Wyo., for duty.

McCallum, Francis M., contract surgeon, upon being relieved at Fort D. A. Russell, Wyo., by Contract Surgeon Miller, ordered to proceed to Camp McKinley, Honolulu H. I., for duty.

Treuholtz, Clarence A., contract surgeon, ordered from General Hospital, Fort Bayard, N. Mex., to Fort Apache, Ariz., for temporary duty.

Pinquard Joseph, contract surgeon, reports return to Fort Leavenworth, Kans, for duty.

Boak, S D, dental surgeon, returned from leave of absence to Columbus Barracks, Ohio for duty

Jordan, Edward H, contract surgeon, ordered to proceed from Denver, Colo, to San Francisco Cal, and take transport to sail from the latter place on or about Sept 5, 1906 for the Philippine Islands and upon arrival at Manila to report in person to the commanding general, Philippines Division, for assignment to duty

Merrick John N, contract surgeon, reports return to duty at Fort Missoula, Mont

Navy Changes

Changes in the Medical Corps, U. S Navy, for the two weeks ending Aug 11, 1906:

Longabaugh, I, acting asst surgeon, appointed acting asst surgeon from Aug 7, 1906

Jones, A McK, acting asst surgeon appointed acting asst surgeon from Aug 7, 1906

Smith H L acting asst surgeon, ordered to the Naval Hospital, Philadelphia

Moore, J M, surgeon, ordered to the *Puritan*

Parker, E G, surgeon, commissioned a surgeon in the Navy from March 24, 1906

Minter, J M, asst surgeon, appointed an asst surgeon in the Navy from Aug 1, 1906

Downey, J O asst surgeon, appointed an asst surgeon in the Navy from Aug 1, 1906

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non commissioner officers of the Public Health and Marine Hospital Service for the seven days ending Aug 15, 1906

Austin H W, surgeon, relieved from duty at Detroit, on arrival of Passed Asst-Surgeon Grubbs at that port, and directed to proceed to San Francisco relieving Surgeon H W Sawtelle and assuming command of the station at that port

Mead F W, surgeon, granted leave of absence for one month from August 15

White J H, surgeon, directed to proceed to Mobile, Ala, for special temporary duty, on completion of which, to rejoin station at New Orleans

Woodward, R M, surgeon detailed to represent the Service at the meeting of the British Medical Association at Toronto, Canada, August 21 to 24

Rosenau, M J, passed asst surgeon, granted leave of absence for one day, August 11, under paragraph 189 of the Regulations

Lavinder, C H, passed asst surgeon, granted leave of absence for twenty eight days from August 11

Grubbs, S B passed asst surgeon, on expiration of present leave of absence relieved from duty at Cleveland Ohio, and directed to proceed to Detroit and assume temporary command of the Service at that port

Anderson, J F, passed asst surgeon, granted leave of absence for five days from August 7, on account of sickness

Duffy, F, acting asst surgeon granted leave of absence for seven days, from August 14

Dunn, James, acting asst surgeon, granted leave of absence for seven days, from August 6, under paragraph 210, of the Regulations

O Reilly, W. J, acting asst surgeon, granted leave of absence for two days, from August 28

Ranson S A, acting asst surgeon, granted leave of absence for thirty days, from September 24, and excused for a further period of sixty days, from October 24

Savage W L, acting asst surgeon granted leave of absence for thirty days from August 11

Sill, R H, acting asst surgeon, granted leave of absence for fifteen days, from August 17

Richardson S W, pharmacist, granted leave of absence for seven days from August 18 under paragraph 210 of the Regulations

Scott, E B, pharmacist granted leave of absence for four days from July 26 on account of sickness

Scott E B pharmacist granted leave of absence for three days, from July 31 on account of sickness

BOARD CONVENED

Board convened to meet at Cebu Philippine Islands for the purpose of examining Pharmacist C R McBride, to determine his fitness for promotion to the grade of Pharmacist of the Second Class Detail for the Board, Passed Asst Surgeon V E Heiser Chairman Passed Asst Surgeon Carroll Fox, Recorder August 13, 1906

Health Reports.

The following cases of smallpox yellow fever cholera and plague have been reported to the Surgeon General Public Health and Marine Hospital Service during the week ended August 17 1906

SMALLPOX—UNITED STATES

Illinois Galesburg July 28 August 4 2 cases
Louisiana New Orleans July 28 August 4 9 cases 2 deaths
Michigan Detroit, July 28 August 4, 2 cases
Missouri St Joseph July 28 August 4, 1 case
New Jersey Elizabeth, June 30 July 7, 1 case
New York New York August 4 11, 1 case
Pennsylvania Columbia, July 28 August 4 1 case
Texas Greenville, March 26 August 6 33 cases
Washington Spokane, July 1 31, 1 case
Wisconsin Appleton July 28 August 4 3 cases; Milwaukee, July 14 21, 1 case; August 4 11, 1 case

SMALLPOX—FOREIGN

Africa Cape Town June 30 July 7, 1 case
Argentina Buenos Ayres May 1 31 197 deaths
Brazil Pernambuco, June 15 30, 2 deaths
China: Hongkong June 9 30, 4 cases, 3 deaths; Shanghai, June 23 30, 1 case, 1 death
France: Paris, July 14 21, 8 cases
Great Britain: Liverpool, July 21 28, 4 cases
Chile: Antofagasta, June 21-July 5, 33 cases, 3 deaths
India: Bombay, June 26 July 10, 7 deaths, Calcutta, June 23 30, 19 deaths; Madras, June 30 July 6, 4 deaths; Rangoon, June 23 30, 4 deaths
Italy: General, July 12 19, 4 cases
Russia. Moscow, June 30 July 21, 11 cases, 7 deaths; Odessa, July 14 21, 5 cases, 2 deaths, St Petersburg, June 30 July 7, 6 cases, 2 deaths
Siberia: Vladivostok, June 14 28, 2 cases

YELLOW FEVER.

Cuba: Habana, August 15, 1 case
Mexico. Merida, July 22 28, 12 cases, 7 deaths; Tierra Blanca, August 12, 1 case; Vera Cruz, July 22 28, 1 case, 1 death (imported from Merida).

CHOLERA

Philippine Islands: Manila, June 23 30, 41 cases, 40 deaths; Provinces, June 23 30, 117 cases, 71 deaths
India: Bombay, June 26 July 10, 78 deaths, Calcutta, June 23 30 28 deaths; Karachi, July 1 8, 1 case, 1 death; Madras, June 30 July 6, 17 deaths; Rangoon, June 23 30, 4 deaths

PLAGUE

Australia: Brisbane, June 20, 1 case 1 death, Sydney, June 23, 1 case, 1 death
Chile Antofagasta, June 21 July 5, 5 cases, 1 death
China: Hongkong, June 9 30, 112 cases, 93 deaths
India: General, June 23 30, 896 cases, 769 deaths; Bombay, June 26 July 10, 71 deaths Calcutta, June 23 30, 23 deaths; Karachi, July 1 8, 24 cases, 17 deaths; Rangoon, June 23 30, 137 deaths
Japan: Formosa, June 1 July 10, 671 cases, 640 deaths

Travel Notes

DISEASES AND HOSPITALS OF THE EAST COAST OF AFRICA.

NICHOLAS SENN, M.D.
Professor of Surgery in the University of Chicago; Professor and Head of the Surgical Department, Rush Medical College
CHICAGO.

Salisbury, Mashonaland, June 8, 1906.

GERMANY'S BATTLE WITH TROPICAL DISEASES IN EAST AFRICA.

(Concluded from page 532.)

TUBERCULOSIS.

No cases of tuberculosis have been seen among the natives living on the mountain plateaus in the interior. On the lowlands, and especially on the coast, where natives come most frequently in contact with foreigners, isolated cases of pulmonary tuberculosis are beginning to come to the notice of physicians, and I saw a few cases in the hospitals I visited. There is every reason to fear that this disease will become more and more prevalent, despite the efforts made to prevent its spread. The lung appears to be the organ pre-eminently predisposed to infection, as all the physicians whom I have met on the coast have never seen any cases of glandular, bone or joint tuberculosis, and among the thousands of natives that came under my observation I failed to find any of the remote results of these affections in the form of scars, kyphosis and ankylosis

RELAPSING FEVER AND SLEEPING DISEASE

This disease has no connection whatever with malarial infection It is a disease *per se*, caused by the bite of a tick found constantly in the huts of natives, more especially along the highways of inland trade and travel The traveler can protect himself against this disease by avoiding stopping-places along caravan routes and entering native huts and by sleeping in a tent at least twenty to fifty feet away from any possible sources of coming in contact with the tick, and by insisting that his servants do the same

The tsetse fly is the most formidable enemy of man and beast in East Africa The commission appointed by the imperial government of Germany is now engaged in throwing more light on the disease caused by infection with the parasite carried and transmitted by this fly.

One of the earliest accounts of tsetse fly and the disease caused by it was given by Dr. David Livingston, the intrepid explorer and devoted missionary, fifty years ago, when he explored the upper Zambesi region. It is interesting reading just now and I will quote from it: 'The tsetse fly, *Glossina* *morsitans*, is a little longer than the ordinary housefly and is nearly of the same color as the honey bee. The upper part of the body has three or four yellow bars across it; the wings project beyond this point considerably, and it is remarkably alert, avoiding most dextrously all attempts to capture it with the hand at common temperatures; in the cool of the mornings and evenings it is less agile. Its peculiar buzz when once heard can never be forgotten by the traveler. It is well known that the bite of this poisonous insect is certain death to the ox, horse and dog.

"The poison does not seem to be injected with a sting or by ova placed below the skin, for when one is allowed to feed freely on the hand it is seen to insert the middle prong of three portions, into which the proboscis divides, somewhat deeply into the true skin; it then draws it out a little way, and it assumes a crimson color as the mandibles come into brisk operation. The previously shrunken belly swells out, and if left undisturbed the fly quickly departs when it is full. A slight itching irritation follows, but not more than in the bite of a mosquito. In the ox this same bite produces no more immediate effects than in man. It does not startle him as the gadfly does, but a few days afterward the following symptoms supervene: The eye and nose begin to run, the coat shivers as if the animal were cold, a swelling appears under the jaw and sometimes at the navel; and, though the animal continues to graze, emaciation soon ensues, accompanied with a peculiar flaccidity of muscles, and proceeds unchecked until, perhaps, months afterward, purging comes on, and the animal, no longer able to graze, perishes in a state of extreme exhaustion. In the acute form the animal often perishes soon after the bite with staggering and blindness, as if the brain were affected by it."

He details the postmortem appearances as found in dead animals, from which he concludes the poison is in the blood. "The poison germ, contained in a bulb at the root of the proboscis, seems capable, although very minute in quantity, of reproducing itself, for the blood after death by tsetse is very small in quantity and scarcely stains the hands in dissecting." This was written half a century ago and much of it has been confirmed since by more extended and modern means of research.

F. Stuhlmann, of the Amani Institute in German East Africa, two hours by rail from Tanga, has written a classical article on the "Anatomy and Physiology of the Tsetse Fly." The amount of work done in obtaining the material for this article is simply stupendous and illustrates to perfection with what thoroughness the German scientists have undertaken the task assigned to them. He found the *Glossina fusca* more common at Amani than the *Glossina tachioroides* and *Glossina palpalis* of Uganda, and it is yet a question to be determined which one of the several varieties of tsetse fles is the most common cause of trypanosomiasis. He kept the flies for months in glass vessels covered with gauze and fed them, say every four or five days, by applying the gauze end of the glass to the skin of a heifer, so that the flies could sting the animal through the gauze cover. He studied the habits of the flies. When the fly alights on the skin it changes its place several times until it finds the right spot, when the puncture is quickly made and the suction is completed in from thirty to forty seconds. The sting feels like the prick of a needle, and the fly is full and withdraws the proboscis in one-half to three-quarters of a minute. He gives a most elaborate description of the proboscis and alimentary canal, which must be read in the original to be understood. In regard to the former he winds up by saying that it resembles that of the housefly in every particular, with the exception that the upper lip has a large, movable pair of labella, which in the ordinary fly are rudimentary. Until recently it was believed that the *Glossina morsitans* was the only cause of the sleeping disease that year after year has destroyed hundreds of herds of cattle and thousands of human beings. Koch is now of the opinion that the disease can also be communicated by the *Glossina fusca* and *Glossina pallidis*. However, further researches and observations are necessary to substantiate or to correct this view. Of the domestic animals only goats, sheep and fowls are immune to the tsetse-fly infection. Natives are much more susceptible to it than Europeans. So far the disease has proved uniformly fatal. It pursues an unusually chronic course, and the symptoms in many respects resemble those described by Livingston as he observed the disease in cattle. It begins as an acute affection, but passes into a chronic form, characterized by hebetude and somnolence, progressive anemia and emaciation. Professor Ollwig was the only physician on the coast that I met who had ever seen a case. Tsetse flies are very numerous in the neighborhood of Dar-es-Salaam, but evidently they do not carry the essential microbic cause of trypanosomiasis, probably because the wild buffalo, formerly so common here, has migrated further north in the direction of Lake Victoria Nyanza, a locality in which the sleeping disease is now most prevalent.

ANKYLSTOMIASIS.

This parasitic disease is extremely prevalent among the natives all along the East Coast of Africa, but Europeans are seldom affected with it. I saw a number of cases in every hospital I visited. Progressive anemia and emaciation are the constant results. Thymol in half-dram doses has so far been employed in its treatment, but the results have not been satisfactory, as relapses only too often follow an apparent cure in consequence of incomplete removal of the essential parasitic cause. Oil of eucalyptus, praised recently by a Dutch physician, is now on trial in the hospital for natives at Dar-es-Salaam. My traveling companion, Dr. L. L. Seaman, made a specialty of this disease in Porto Rico and is enthusiastic over the curative effects of beta-naphthol in half-dram doses, followed twelve hours later by a brisk saline cathartic. This remedy will be given a trial in the hospitals here.

BUBONIC PLAGUE.

This, one of the pests of the tropics, threatens German East Africa from the north. It had its origin in the interior of Africa about the source of the Nile, whence it spread to Uganda and finally reached the northern boundary of German East Africa, where two foci were established. The strict sanitary measures employed and the quarantine enforced to prevent its further spread will undoubtedly prove eminently successful.

APPENDICITIS.

After visiting the hospitals at Mombasa, Tanga and Dar-es-Salaam and conversing with the physicians, I learned that none of them had ever seen a case of appendicitis among the blacks, and most of them had lived on the coast from two to twelve years, and in the aggregate had examined thousands of cases. The relaxing effects of the climate, the notorious laziness of the people, but more especially the almost exclusive vegetable and fruit diet, go far to explain the almost complete immunity to the disease that afflicts so frequently Europeans and Americans and fills the case books and the operating rooms of our surgeons.

CARCINOMA.

From all the information I could gather from physicians on the East Coast of Africa and at Zanzibar, carcinoma is almost unknown as a disease of the blacks in the tropic region of Africa. On close inquiry I was able to find only two well-authenticated cases, one of carcinoma of the stomach at Dar-es-Salaam and the second a case of epithelioma of the lower lip, observed by Dr. Friedrichsen, of Zanzibar.

The diagnosis in the first case was confirmed at the operation performed, and in the second case by the clinical course of the disease, which was characterized by all the clinical symptoms of this disease from the beginning to the fatal termination. The radical operation recommended by the physician when the disease was still in an operable stage was refused, and it pursued its usual relentless course. It was this exemption from carcinoma of the natives living in the tropics and in the Arctic regions that led me to the conclusion that carcinoma is caused largely by unknown climatic and dietetic influences, for the international study of which I made a plea in one of the general sessions of the International Medical Congress at Lisbon.

MEDICAL SCHOOLS OF THE UNITED STATES

Below is given a brief description of the medical colleges in the United States that are legally chartered to confer the degree of doctor of medicine, and whose diplomas are recognized by at least one state licensing board. The list includes the sectarian as well as the regular colleges, as their graduates are physicians in the eyes of the law. The information given is, as a rule, obtained from the catalogues and has been submitted to the dean of each school for his inspection and approval. Colleges which belong to the American or the Southern Medical College Association or other organization of colleges have requirements for admission of students according to the rules of these associations, unless their requirements are higher, in which case a statement is made to that effect. Extracts from these rules are given at the close of the list of colleges.

ALABAMA.

Alabama, population 1,828,697, has two medical colleges, the Medical College of Alabama and the Birmingham Medical College, located in Mobile and in Birmingham. The population of Mobile is 40,686 and of Birmingham 42,087. Board and room may be obtained from $12 to $20 per month.

Birmingham.

Birmingham Medical College.—This school was incorporated in 1894 and is situated in Birmingham. The clinical advantages are good. The Hillman, St. Vincent's, Pratt and County hospitals are accessible to the students. The laboratories are well equipped. There are 19 professors and 9 assistants, total 28. The school is a member of the Southern Medical College Association. The course of instruction embraces four separate sessions of six months each. The fees are $75 for each of the first three years and $100 for the fourth. The Dean is Dr. B. L. Wyman. Registration, 1905-6, 72; graduates, 8. Next session open Oct. 3, 1906, and closes April 3, 1907.

Mobile.

Medical College of Alabama.—This is the Medical Department of the University of Alabama, organized in 1859. The city Hospital furnishes free clinical material. The faculty consists of 8 professors and 9 lecturers, 17 in all. It is well equipped with building, laboratories, dispensary, etc. It is a member of the Southern Medical College Association. The course of study covers four years of seven months each. The total fees for each of the first three years is $100; for the fourth year, $125. The Dean is Dr. George A. Ketchum. Total registration, 1905-6, 158; graduates 29. The forty-first session will begin Oct. 1, 1906, and will close April 30, 1907.

ARKANSAS.

Arkansas, population 1,311,564, has two medical colleges, both located in Little Rock, a city of 42,036 people. Board and lodging cost from $13 to $18 per month.

Little Rock.

University of Arkansas Medical Department.—This college was organized in 1879 as the Arkansas Industrial University Medical Department. The teaching body consists of 15 professors and 20 lecturers and assistants, total 35. Hospital facilities are furnished by Logan H. Roots Memorial Hospital, St. Vincent's Infirmary and Pulaski County Hospital, the latter having a capacity of 200 beds. The course of study covers four years of seven months each. Dr. F. L. French, Little Rock, is Secretary. The fees are: Matriculation $5, paid but once; annual fees $60, and graduation $25. Total number of students at last session, 176; graduates, 26. The next course of lectures begins Oct. 1, 1906, and ends May 1, 1907.

College of Physicians and Surgeons.—This college was organized in 1906 and has a faculty of 21. It will occupy the buildings formerly used by the Maddox Seminary. The Dean is Dr. J. P. Runyan and the Secretary, Dr. W. P. Illing. The first session will begin Oct. 1, 1906.

CALIFORNIA.

California, population 1,485,053, has nine medical colleges. Six are located in San Francisco, a city having, before the earthquake, 355,919 inhabitants. They are Cooper Medical College, Medical Department of the University of California, California Medical College, Hahnemann Medical College of the Pacific, the College of Physicians and Surgeons and the West Coast. The clinical facilities of San Francisco are good. Board and lodging can be obtained for from $20 to $30 a month. The College of Medicine of the University of Southern California is situated in Los Angeles, population 116,420. Board and lodging can be obtained in that city for $4 a week and upward. The Oakland College of Medicine and Surgery is in Oakland, population 70,386.

Oakland.

Oakland College of Medicine and Surgery.—Organized in 1902; first class grandated in 1905. The fifth session of this school will begin Aug. 21, 1906, and end May 14, 1907. The length of the course is nine months. The classes are limited to ten students each. The Registrar is Dr. Edward N. Ewer. The faculty numbers 28. Tuition is $160 yearly. Total registration, 1905-6, 10; graduates, 4. The next session begins Aug. 21, 1906, and ends May 14, 1970.

San Francisco.

Cooper Medical College.—This school was organized in 1858, though its present name was not adopted until 1882. The faculty consists of 17 professors and 44 lecturers, instructors, etc., 61 in all. Lane Hospital, adjoining the college, the City and County Hospital, containing 464 beds, and the college dispensary furnish clinical material. The minimum requirements for admission are a certificate showing that applicant has passed the regular examination for admission to the University of California, or its equivalent, or graduation from an accredited high school, academy, or preparatory school. The college itself does not hold entrance examinations. The college building supplies large laboratory and lecture-room facilities. The curriculum covers a graded course of four years of eight and a half months each. Fees: Matriculation, $5; course fee for each year, $150; laboratory fee for each year, $10; breakage deposit each year, $10; graduation fee, $25; no other charges. The Dean is Dr. Henry Gibbons, Jr. Total registration for 1905-6 was 138; graduates, 30. The next session opens Aug. 15, 1906, and will close May 8, 1907.

University of California Medical Department.—This department of the State University was organized in 1872, and has a faculty composed of 18 professors, 44 associates and assistants, a total of 62. The City and County Hospital, which admits students of this school not only to the clinics proper, but also to its wards for study, and the college dispensary furnish good clinical material. The course covers graded work for four years of nine months each. This school is a member of the Association of American Medical Colleges. Two full college years' work is required for all applicants for admission. The fees are: Matriculation, $5; tuition, $150 each year; laboratory fees extra. The Dean is Dr. Arnold A. D'Ancona. Total registration for 1905-6, was 90; graduates, 19. The thirty-fourth session opens Aug. 15, 1906, and will close May 15, 1907.

College of Physicians and Surgeons of San Francisco.—This school was organized in 1896 and has a faculty of 28 professors and 15 associate professors and teachers, a total of 43. The hospital facilities consist of the City and County Hospital, the California General Hospital, with 50 beds, and St. Winifred Hospital, with 50 beds. The daily clinics at the new college building furnish abundant material of every description. Applicants for matriculation must show a high school diploma or equivalent credentials, or be examined by the State Superintendent of Public Instruction in high school studies. The college building recently completed is well supplied with laboratories and lecture rooms. Attendance upon four terms of at least 30 teaching weeks each, is required for graduation. Fees, $100 per year. The Dean is Dr. D. A. Hodghead. Registration for 1905-6 was 145; graduates, 30. The next session opens Sept. 17, 1906, and closes May 17, 1907.

Hahnemann Medical College of the Pacific.—Homeopathic. This school was organized in 1884, and has a faculty of 19 professors and 23 lecturers, instructors, etc., in all 42. The Pacific Homeopathic Polyclinic, the Hahneman Hospital, the San Francisco Nursery for Homeless Children, Marie Kip Orphanage, accommodating, respectively, 45, 75 and 120 beds; Fabiola Hospital and the City and County Hospital, furnish the clinical material for study. Matriculants must possess the equivalent of a high school education. One year after entrance is permitted in which the student may complete conditions in Latin. The college is registered and accredited with New York State Regents and the Illinois and Michigan State Boards of Health. The course includes four years of seven months each. Total fees for the first year, $155, and $100 for each of the other three years. The Dean is Dr. James W. Ward, 606 Sutter St., San Francisco. Total registration for 1905-6, was 24; graduates, 4. The twenty-fourth session begins Sept. 12, 1906, and will close May 23, 1907.

California Medical College.—Eclectic. This school was organized in 1884 and has a faculty of 10 professors and 25 lecturers, and instructors, a total of 35. The clinical material is supplied by the Buena Vista and City and County Hospitals. Applicants for admission not holding diploma or certificate are examined. The course has been extended to cover four years of eight months each. Total fees are about $110 for each of the first three years and $40 for the fourth year. The Dean is Dr. D. Maclean. Total registration for 1905-6 was 36; graduates, 10. The next session begins Oct. 2, 1906, and ends May 16, 1907.

West Coast Medical College.—Organized in 1900 as the Pacific Coast College of Medicine. Name changed to the above in 1902. Had 31 graduates in 1903. Course was five years of seven months each. Destroyed by the earthquake and fire, April, 1906. The Dean is Dr. C. W. W. von Tiedemann.

Los Angeles.

University of Southern California College of Medicine.—This school was organized in 1835, and has a faculty of 29 professors and 19 instructors, 48 in all. The County Hospital having 200 beds, the Sisters' Hospital of 150 beds, the Children's Hospital of 20 beds, and a college dispensary furnish clinical material. Applicants for admission must give evidence of matriculation in a university or graduation from an accredited high school, academy, preparatory school or a California State Normal School, or a certificate from the Deputy State Superintendent of Schools, that applicant has filled the requirements of the Association of American Medical Colleges, of which this college is a member. This college gives no admission examinations. The building is provided with laboratories, amphitheater and lecture rooms, and a new clinical laboratory, erected in 1904, costing, with equipment, $25,000. The Barlow Medical Library building will be opened Oct. 5, 1906. A graded course, covering four years of thirty-two weeks each, is offered. The total fees for the first year are $145; second and third, $150 each, and $40 for the fourth year. The Dean is Dr. Walter Lindley. Total registration for 1905-6 was 128; graduates, 28. The next session opens Oct. 4, 1906, and closes June 13, 1907.

College of Physicians and Surgeons.—This school was organized in 1903. The length of each course is eight and one-half months. The faculty numbers 37 in all, 24 professors, 6 associate professors, 3 lecturers, and 4 instructors, besides a corps of clinical assistants. The registration for 1905-6 was 31; graduates, 3. The next session begins Oct. 4, 1906, and ends June 18, 1907. The Dean is Dr. Charles W. Bryson, Delta Bldg., Los Angeles.

COLORADO.

Colorado, with a population of 539,700, has three medical colleges. Two of these, Denver and Gross College of Medicine and Denver Homeopathic College, are in Denver, which has a population of 144,588; the other, the Colorado School of Medicine, is at Boulder, population 6,150. The clinical facilities in Denver available to the two colleges are the Denver County Hospital, which has a capacity of 300 beds; St. Joseph's Hospital, with 300 beds, and St. Luke's Hospital, with 75 beds. The Public Library contains 10,000 volumes on medicine. Board can be obtained in Denver for $5 a week and upward.

Denver.

The Denver and Gross College of Medicine.—This is the Medical Department of the University of Denver, and was organized in 1902 by the union of the Gross Medical College (organized 1887) and the Denver College of Medicine (organized 1880). The clinical advantages are the college dispensary, the Denver County Hospital, St. Luke's Hospital, St. Anthony's Hospital, St. Joseph's Hospital, National Jewish Hospital for Consumptives, Home for Dependent Children and the City Contagious Hospital and Mercy Sanitarium. The faculty is made up of 36 professors, 40 assistants and instructors, a total of 76. Its location is central, and the buildings are well arranged for laboratory, dispensary and didactic work. The course is graded and covers four years of eight months. The college is a member of the Association of American Medical Colleges. Final examinations at the end of each year are held. Fees for the first year are $115. For the second year, $116. Third year, $101. Fourth year, $126. Total registration, 1905-6, was 100; graduates, 26. The twenty-fifth session will begin Sept. 11, 1906, and close May 18, 1907. The Dean is Dr. S. G. Bonney.

Denver Homeopathic College.—This college, organized in 1894, beside clinical privileges in the hospital of the city and county of Denver, has exclusive privileges for clinical work in the Denver Homeopathic Hospital, the Haven, the Belle Lenox Nursery, and the Tabernacle Free Dispensary. The faculty numbers 26 professors and 7 lecturers and instructors, 33 in all. The requirements for admission are, "possession of a diploma from a literary college, university, an academy, a normal or high school; a first-grade teacher's certificate, or a previous matriculation at some reputable literary or medical college." The course of study consists of four years of eight months each. The year is divided into semesters. Examinations are held at the end of each semester in the work completed. A five-year scholarship may be had for $300 payable in advance, otherwise the tuition is $100 a year for the first, second and third years. Senior year, $75. There is a matriculation fee of $5, payable once. The Dean is Dr. Joseph B. Kinley. Total registration for 1905-6 was 23; the number of graduates, 5. The twelfth session begins Sept. 17, 1906, and will close May 8, 1907.

Boulder.

Colorado School of Medicine.—This is the Medical Department of the University of Colorado, and was opened in 1883. The University Hospital, under the control of the state, is equipped to accommodate 40 patients, and furnishes free clinical material. Both hospital and dispensary clinics are offered and the sanatorium located at Boulder offers additional advantages in this line. The faculty embraces 18 professors and 9 lecturers and assistants, a total of 27. The laboratories are well equipped and commodious. A separate building is devoted to the study of anatomy and another one is used for medical work exclusively. A complete four-year course of study in a recognized high school, or its equivalent, is required for admission. This school is a member of the Association of American Medical Colleges. The work embraces a graded course of four years of nine months each. The tuition is $50 per year; there are no other fees. The Dean is Dr. Luman M. Giffin. Total registration for 1905-6 was 70; graduates, 16. The twenty-fifth session begins Sept. 11, 1906, and closes June 7, 1907.

CONNECTICUT.

Connecticut, with a population of 908,420, has only one medical college, located in New Haven, population 114,600. Board and lodging cost $4.50 and upward per week.

New Haven.

Yale Medical School.—This is the Department of Medicine of Yale University. In 1810 a charter was granted for the establishment of this school, and in 1813 it was organized as the Medical Institution of Yale College. In 1879 a new charter changed the name to the one now used, and in 1884 the Connecticut Medical Society, which, from the granting of the first charter, had taken University authorities assumed full control. The clinical advantages are embraced under the New Haven Hospital, which contains 175 beds and is the general hospital for New Haven; the Springside Hospital, which is connected with the city almshouse, and the State Hospital for the Insane, located in Middletown, about twenty-five miles distant, which, with its 1,800 patients, offers an opportunity for special instruction in insanity in addition to the clinics. Beside these, the University has just completed a $100,000 building for the dispensary service, which offers good material for clinical teaching. The faculty embraces 12 professors, lecturers and assistants, 42, a total of 54. The lecture rooms and laboratories are large and well equipped. Matriculants are admitted without examination, provided that they have received a degree in arts or sciences, that they present certificates showing that they have successfully prosecuted the subjects of the examination at some college, high school, academy or preparatory school approved by the faculty, or that they have passed matriculation examinations equivalent to those required at some approved professional school. The course covers a four-year graded curriculum, nine months constituting a school year; the first two years the fundamental branches are studied, the third year is devoted to a systematic teaching of medicine, surgery, obstetrics and pharmacology, and in the fourth year clinical work, with medicine, surgery and the specialties, is presented. The fees are $150 each year; in the first year there are additional fees amounting to $18, and in the second, $8, and there is a graduation fee of $10. The Dean is Dr. Herbert E. Smith, New Haven. During the session of 1905-6, there were 134 matriculants and 25 graduates. The ninety-fourth session opens Sept. 27, 1906, and closes June 26, 1907.

DISTRICT OF COLUMBIA.

Washington, population 293,217, has three medical colleges; George Washington University Department of Medicine, Georgetown University School of Medicine and Howard University Medical Department. Washington offers to the student of medicine many advantages. The Army Medical Museum, the Museum of Hygiene, the National Museum, the library in the surgeon-general's office, the Toner Medical Library, and Museum of Hygiene, in all over 125,000 volumes on medicine, open to the medical student a most profitable field. The clinical advantages offered by the various hospitals are good. Owing to the many boarding houses and hotels, board and lodging can be had at reasonable rates.

Washington.

The George Washington University, Department of Medicine.—This school was organized in 1821 as the Department of Medicine of Columbian College, which in 1873 became Columbian University, and in 1904, by an act of Congress, changed its name to the George Washington University. In connection with the Department of Medicine is the University Hospital, established and maintained to afford clinical facilities for the students of the school. Beside the University Hospital, the Garfield Hospital, the Children's Hospital, the Central Dispensary and Emergency Hospital, the Providence Hospital, the Columbia Hospital, the Episcopal Eye and Ear Hospital, the U. S. Government Hospital for the Insane, and the Lutheran Eye and Ear Infirmary afford additional opportunities and are utilized for clinical instruction. Attendance on clinics is obligatory on third and fourth-year students. The faculty is composed of 38 professors and 41 demonstrators, instructors and assistants. This school is a member of the Association of American Medical Colleges. The laboratories are modern and equipped with all the needed apparatus for thorough work and instruction. The college library contains 2,000 volumes as well as the best current medical periodicals. Beginning with the session of 1909-10 matriculants must present credentials of two years' satisfactory work in an approved college of liberal arts or its equivalent. A combined course of six years' work, leading to the degrees of A.B. and M.D. is offered. The course of instruction is graded and extends through four years, each scholastic year consisting of eight months. Written and practical examinations are held during the term and written and oral in all subjects at the end of the school year. The total fees for the first year are $157; for the second year $152; for the third year, $112, and for the fourth year, $162. A breakage deposit of $5 is required. The Dean is Dr. W. F. R. Phillips, 1607 16th St. N. W. New and commodious buildings were erected and occupied in 1902. The total registration of students for the session of 1905-6 was 280; graduates, 51. The eighty-fifth session begins Sept. 26, 1906, and closes June 5, 1907.

Georgetown University School of Medicine.—This school organized in 1850, controls the Georgetown University Hospital, which affords excellent facilities for clinical teaching and ward classes Clinics are also held for the benefit of the students in Providence Hospital, containing 500 beds, at the Government Hospital for the Insane, containing over 2,000 beds; in the Children's Hospital, the Central Dispensary, Emergency Hospital and the Garfield Hospital Attendance on clinical instruction is obligatory in the third and fourth years. The faculty contains 19 professors, 35 instructors and assistants, total 54. This school is a member of the Association of American Medical Colleges. The building is conveniently located and contains spacious and well-ventilated lecture rooms, laboratories and library; the laboratories are equipped with the most approved instruments and appliances. The complete course of study extends over four terms of eight and one-half months each. Examinations are held at the end of each session. The fees are $150 each year. The Dean is Dr. George M. Kober, 1600 T St. The registration for 1905-6 was 102; graduates, 20. The next term opens on Sept. 27, 1906, and ends June 11, 1907.

Howard University Medical Department.—This institution was organized in 1867, and "in conformity with the spirit of the organic law of the University, is open to all, without regard to sex or race, who are qualified by good moral character, proper age and suitable education." The removal of any racial distinction has been taken advantage of by colored students, who compose a majority of those in attendance, but a number of white students are also receiving instruction. The Freedman's Hospital is a general hospital of 300 beds. The faculty comprises 17 professors and 27 lecturers and assistants, 44 in all. This college is a member of the Association of American Medical Colleges. Students are required to attend four courses of lectures in separate years of eight months each. The fees of each session are $80, plus $2 per part for dissecting material, and $10 for graduation. Board can be had at the school dining hall for $9 a month, and a room in the dormitory for $15 a term. The Dean is Dr. Robert Reyburn, 2129 F St. Registration for 1905-6 was 157; graduates, 29. The thirty-ninth session begins Oct. 1, 1906, and closes June 1, 1907.

GEORGIA.

Georgia, population 2,216,331, has four medical colleges; Medical College of Georgia, located in Augusta, population 41,283; Atlanta College of Physicians and Surgeons, Atlanta School of Medicine, and Georgia School of Eclectic Medicine and Surgery, are in Atlanta, a manufacturing city of 96,550 population. Board and lodging may be obtained for from $3 to $5 per week.

Augusta.

Medical College of Georgia.—This school was organized as a medical academy in 1829, and in 1873 was made the Medical Department of the University of Georgia. Its faculty includes 14 professors and 14 assistants, 28 in all. The course is four years of seven months each. Applicants for admission must, by examination, certificate or diploma, show that they possess educational qualifications equal to those required for second grade teachers in public schools; if they are deficient on examination, however, they are admitted, and they may remove the conditions any time before they appear for graduation. The City Hospital, with 130 beds; Lamar Hospital, with 80 beds; the Polyclinic and the Hospital for Contagious Diseases supply clinical material. Fees for the first two years are $75 each; third year, $100, and $130 for the last year. The Dean is Dr. Joseph Eve Allen. The total enrolment for 1905-6 was 118; graduates, 30. The seventy-fifth session begins Oct. 1, 1906, and closes May 1, 1907.

Atlanta.

Atlanta College of Physicians and Surgeons.—This school was formed in 1898 by the consolidation of the Atlanta Medical College, organized in 1854, with the Southern Medical College, organized in 1879. It has a faculty of 16 professors and 17 assistants, a total of 33. Clinical facilities are furnished by the Grady Hospital, which is the general hospital for Atlanta, clinics are free to the graduating class. First course students are required to "give satisfactory evidence to the faculty of such educational qualifications as will be deemed necessary for the successful prosecution of their medical studies. These requirements will be similar to those of other reputable medical colleges in the country." The course of study covers four years of seven months each and is graded. The buildings are large and a new building for didactic lectures and clinical work has been added. Fees: First and second years, $75 each; third and fourth, $100 each. The Dean is Dr. W. S. Elkins, 29 Luckie St. Total registration of students for 1905-6 was 182; graduates, 52. Next session begins Oct. 1, 1906, and closes April 30, 1907.

Georgia College of Eclectic Medicine and Surgery.—This school was organized in 1839, and has a faculty of 16. The college dispensary, Grady Hospital and Georgia Eclectic Hospital furnish clinical material. Applicants for admission must adhere to the requirements established in the National Confederation of Eclectic Colleges, of which this college is a member. The curriculum covers four years of six months each. The Proctor is Dr. Elzie B. Thomas, 121 Park St., West End. Total number of students for 1905-6 was 57; graduates, 15. The next session opens Oct. 3, 1906, and closes April 1, 1907 (about).

Atlanta School of Medicine.—This school was organized in 1905. A new building is now being constructed which will be completed by Sept. 15, 1906. Session of 1905-6 covered six months, which hereafter will be extended to seven months. Enrolment for 1905-6 was 220. Number of graduates, 21. Next session begins Sept. 26, 1906 and ends April 30, 1907. The Dean is Dr. Geo. H. Noble. The Proctor is Dr. Edward G. Jones.

ILLINOIS.

Illinois, population 4,821,550, has thirteen medical colleges, all located in Chicago, a city of 1,873,880 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, Hahnemann Medical College, Bennett College of Eclectic Medicine and Surgery, College of Physicians and Surgeons, Hering Medical College, Jenner Medical College, Illinois Medical College, American Medical Missionary College, College of Medicine and Surgery, National Medical University, American College of Medicine and Surgery, and Dearborn Medical College. Room and board cost $3 a week and upward.

Colleges in Illinois have to admit students in conformity with the minimum requirements of the Illinois State Board of Health, as follows: "A diploma or certificate of graduation from a high school, or a certificate signed by a principal of a regularly organized high school or by the examiner of the faculty of a recognized literary or scientific college or university, or by the state superintendent of public instruction, or a superintendent of public schools, of having successfully passed an examination in all the several branches embraced in the curriculum of a four years' high school course. The matriculation examination shall not be conducted by any member of the faculty of the medical college. The Illinois State Board of Health will require each applicant for a state certificate to present documentary evidence of his preliminary education, together with his medical diploma, when taking the examination of the board." These conditions will govern all persons admitted to the freshman year on or after Jan. 1, 1903.

All persons admitted to the study of medicine after Jan. 1, 1910, must have had, in addition to the four years' high school course, at least one year of nine months either in a college chartered to grant liberal degrees or in a preliminary year to a medical college, this year to be devoted to the study of physics, chemistry, biology and languages.

Chicago.

Rush Medical College.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 to 1898, and in the latter year became affiliated with the University of Chicago. The faculty is composed of 69 professors, 185 associates, instructors, etc., a total of 254. Good clinical facilities are furnished by Cook County Hospital, caring for about 20,000 patients yearly; Presbyterian Hospital, with 250 beds; a college dispensary, and an obstetric department. In addition to these, extramural clinical courses are offered at the West Side Hebrew Dispensary, St. Luke's Hospital, St. Anthony's Hospital, the Alexian Brothers' Hospital, Illinois Charitable Eye and Ear Infirmary and Chicago Isolation Hospital. Bedside instruction is given. The requirements for admission are those of admission to the better universities or colleges, and, in addition thereto, two years of college work. This college work must have included thorough courses in college chemistry (inorganic, organic and qualitative analysis), college physics and biology, all with laboratory work, a reading knowledge of German or of French. The laboratories and their equipment are adequate. The curriculum covers graded work for four years of three quarters each, a quarter being three months. A fifth year, consisting of a hospital internship or of a fellowship in one of the departments is offered, but, for the present is optional. A continuous session is held, but credit for more than three quarters can not be obtained in any calendar year. A combined course for six years confers degrees of both science and medicine. All freshman and sophomore studies are given at the University of Chicago. The total fees are $180 each year. A matriculation fee of $5 is paid but once, and there are incidentals amounting to from $2 to $5 annually. The Deans are Dr. Frank Billings, 100 State St., and Dr. John M. Dodson, 34 Washington St. Total registration, 1905-6 was 450; graduates, 83. The fiscal year begins July 1; final examinations are held at the end of each quarter.

College of Physicians and Surgeons.—This school was organized in 1881, and in 1896 became the Medical Department of the University of Illinois. The faculty is composed of 42 professors, 156 assistants and instructors, a total of 198. The West Side Hospital, containing 125 beds; Cook County Hospital, and a college dispensary and maternity clinic supply most of the clinical material, but under certain conditions students of this school are admitted to the following hospitals for clinical study: Augustana, Baptist, Chicago, Woman's, Samaritan, Alexian Brothers', St. Mary's and the Chicago Lying-in. This school is a member of the Association of American Medical Colleges. The laboratory, amphitheater and lecture-room space and equipment are excellent. The collegiate year is divided into two terms; the winter term of thirty-six weeks and the summer term of twelve weeks, of actual teaching. Attendance on the winter term is required in order to secure credit for a year's work, and attendance on four winter terms is required for graduation. Attendance on the summer term is optional, and the work is supplementary to the work of the winter term. Students may obtain credit for work done in certain branches, but attendance on this term does not apply on the required thirty-six months' attendance necessary for graduation. The fees are $145 each for the first two years, $150 for the third, and $175 for the fourth year. The Dean is Dr. William E. Quine, 103 State St. Total registration for 1905-6 was 556; graduates, 210. The fall term begins Sept. 25, 1906, and ends June 4, 1907.

Northwestern University Medical School.—This school was organized in 1859 as the Medical Department of Lind University, became independent as the Chicago Medical College in 1864, and in 1869 assumed its present relation as Medical Department of Northwestern University. The faculty comprises 38 professors and 78 assistants and instructors, in all 116. Wesley Hospital, with 225 beds; Mercy Hospital, containing 400 beds; Provident Hospital, 100 beds; St. Luke's, 200 beds; the Chicago Lying-in Hospital, and a college free dispensary furnish opportunities for clinical study to students of this college exclusively. Cook County and the People's hospitals are also open to them for study. Applicants for admission must, by diploma, certificate or examination, show possession of the educational requirements required to enter the College of Liberal Arts of Northwestern University. The laboratory and lecture room facilities are ample and the equipment is good. The course of study covers graded work for four years of thirty-six weeks each. Optional summer laboratory and clinical courses are also given. Final examinations are held at the end of each semester. The fees for each year are $175, and a matriculation fee of $5, paid once, is charged. The Dean is Dr. N. S. Davis, Chicago Savings Bank Bldg. The total registration for 1905-6 was 580; graduates, 125. The next session opens Oct. 2; 1906, and closes June 2, 1907.

American Medical Missionary College.—This school was organized in 1895 and has the primal object of educating men and woman as missionary physicians. The faculty numbers 27. The didactics and laboratory work, covering the first two years, are carried on at Battle Creek, Mich., and the clinical studies in Chicago. A hospital with 20 beds, in connection with the college, together with a free college dispensary with an obstetric department, supply material for practical work. The college is a member of the Association of American Medical Colleges. The course covers four years of nine months each. Total fees are $105 for each of the four years. The Secretary is Dr. E. L. Eggleston, Battle Creek, Mich. Total registration for 1905-6 was 80; graduates, 22. The twelfth session opens Sept. 18, 1906, and closes June 17, 1907.

ILLINOIS MEDICAL COLLEGE.—This school, organized in 1894, has a faculty of 34 professors and 16 assistants, a total of 50. A college dispensary and Cook County Hospital are available for clinical study. The requirements of admission include a high school diploma or its equivalent. The college is a member of the Association of American Medical Colleges. Attendance for seven months during each year is necessary for graduation. Total fees are about $125 for each year. The Dean is Dr. B. B. Eads, 103 State St. Total registration for 1905-6 was 192; graduates, 48. The next fall term begins Sept. 4, 1906.

JENNER MEDICAL COLLEGE.—This is a day and evening school, organized in 1892. The faculty consists of 46 professors and 7 assistants, 53 in all. Cook County Hospital and college dispensary supply clinical material. The course covers four years of 40 weeks each and embraces laboratory, didactic and clinical instruction. The total fees each year are $100, with a $5 matriculation fee, paid but once. The Registrar is Dr. J. G. Tyssowski, 196 Washington St. Total enrolment for 1905-6 was 250; graduates, 38. The next session begins Sept. 3, 1906, and will end June 27, 1907.

DEARBORN MEDICAL COLLEGE.—This school was organized in 1903, with a faculty of 38 professors and 4 assistants, a total of 42. The instruction, which is given in the evening only, extends over a period of five years of ten months each. Cook County Hospital, Samaritan Hospital and a college dispensary supply the clinical material. The total fees are: $5 matriculation fee, $110 tuition, and $10 laboratory deposit. The Dean is Dr. L. Blake Baldwin; the Secretary, Dr. J. L. Wells. Total registration for 1905-6 was 221; graduates, 35. The next session begins Sept. 3, 1906, and ends June 24, 1907.

HAHNEMANN MEDICAL COLLEGE.—Homeopathic. This school was organized in 1855, and has a faculty of 80. Hahnemann Hospital and a college dispensary supply clinical material. The requirements for admission are a high school diploma or its equivalent. The course is four years of eight months each. Fees: Matriculation, paid once, $5; each semester, $50, and hospital tickets, $5 each for third and fourth years. The Registrar is Dr. W. Henry Wilson. Total registration 1905-6 was 178; graduates, 58. The next session begins Oct. 1, 1906, and ends May 29, 1907.

HERING MEDICAL COLLEGE.—Homeopathic. This school was organized in 1892. Dunham Medical College, organized in 1895, was consolidated with it in August, 1902. In January, 1905, it purchased the Chicago Homeopathic College Building at 350 South Wood St., opposite Cook County Hospital, which it now occupies. The faculty comprises 40 professors and 25 associates, lecturers, etc., in all 65. Hering College Hospital, Chicago Homeopathic, Frances Willard and Cook County hospitals supply clinical facilities. The course covers four years of eight months each. The total fees for a full course are $300 if paid in advance, or $100 per year. The Dean is Dr. H. C. Allen. Total registration for 1905-6 was 48; graduates, 14. The fourteenth session begins Sept. 3, 1906, and ends May 3, 1907.

COLLEGE OF MEDICINE AND SURGERY.—Physio-Medical. This school was organized in 1896, and has a faculty of 40 professors and 3 assistants. The college dispensary supplies material for clinical work. The course covers four years of eight months each. Fees for the first, second and third years, $110 each, and $115 for the fourth. The Secretary is Dr. John C. McCandless, 6536 Ingleside Ave. Total registration for 1905-6 was 40; graduates, 5. The next session begins Sept. 26, 1906, and ends May 17, 1907.

BENNETT COLLEGE OF ECLECTIC MEDICINE AND SURGERY.—This school, organized in 1868, has a faculty of 40 professors and 12 assistants, 52 in all. The Bennett, Cook County and Baptist hospitals and a college dispensary supply clinical facilities. Matriculants must present a diploma or certificate or pass a satisfactory examination "in conformity with the minimum requirements of the State Board of Health." The course covers four years of thirty weeks each. This school is a member of the National Confederation of Eclectic Medical Colleges. Fees for each year are $100, with a matriculation fee, paid once, of $5. The Dean is Dr. A. L. Clark, Elgin, Ill. Total registration, 1905 6 was 166; graduates, 52. The thirty-ninth session begins Sept. 25, 1906, and ends May 7, 1907.

AMERICAN COLLEGE OF MEDICINE AND SURGERY.—This school was founded in 1901 and has a faculty of 65. The requirements for entrance are graduation from an accredited high school or equivalent. The course is four years of eight months each. Frances E. Willard and Cook County hospitals supply clinical material. The Secretary is Dr. J. N. Roe. The annual fee is $100; matriculation fee is $5; a total fee for one year, with board, room, light and heat, is $208. The enrolment, 1905-6 was 189; graduates, 23. The next session begins Sept. 24, 1906, and closes May 21, 1907.

NATIONAL MEDICAL UNIVERSITY.—This school was organized in 1891, and its courses include instruction in the methods of all the so-called schools of practice, including manual therapeutics. The faculty numbers 75. The requirements for entrance are in accordance with the requirements of the Illinois State Board of Health. Each year is divided into four quarters of thirteen weeks each, attendance on three quarters constituting one college year. The fees are $200 per year. The Dean is Dr. L. D. Rogers, 533 Wells St. Total matriculants for 1905-6 were 249; graduates, 29. The autumn quarter will begin Oct. 1, 1906.

INDIANA.

Indiana, population 2,516,462, has five medical colleges. Four are situated in Indianapolis, a city of 191,033 people: The Indiana Medical College, the Eclectic Medical College, the Physio-Medical College of Indiana and the State College of Physicians and Surgeons. The clinical facilities of Indianapolis are good, and board and lodging can be obtained from $3 a week and upward. The School of Medicine, Indiana University, is situated in Bloomington, a city of 5,000.

Indianapolis.

INDIANA MEDICAL COLLEGE, THE SCHOOL OF MEDICINE OF PURDUE UNIVERSITY.—Organized in 1869 as The Medical College of Indiana, Medical Department of the University of Indianapolis. In September, 1905, consolidated with Purdue University, The Central College of Physician and Surgeons and the Ft. Wayne College of Medicine, and assumed above title. Total number of students for 1905-6, 339; number graduated, 122. This college is a member of the Association of American Medical Colleges. Total fees, per term, $75. The faculty embraces 50 professors and 60 lecturers, demonstrators and assistants. Four years graded course.

ECLECTIC MEDICAL COLLEGE OF INDIANA.—This school was organized in 1900 and has a teaching force of 24. The course is four years of seven months each. Fees: For each year, $15, or for all four, $225; $25 for graduation. Total registration, 1905-6, 20; graduates, 6. The Dean is Dr. T. M. Culver, 723 So. Meridian St.; the Secretary is Dr. F. M. Wright, 1120 E. 10th St. The next session begins Sept. 21, 1906, and ends April 21, 1907.

PHYSIO-MEDICAL COLLEGE OF INDIANA.—This school was org ized in 1873 and has a faculty of 36. The course is four years eight months each. Total fees for each year are $90. The Sec tary is Dr. C. T. Bedford, Newton-Claypool Bldg. Total enro ment, 1905-6 was 23; graduates, 6. The next session begins Sep 11, 1906, and closes May 9, 1907.

THE STATE COLLEGE OF PHYSICIANS AND SURGEONS.—In affilia tion with the Indiana University. This school was organized this year. The faculty, as selected, is to consist of 26 professors, 10 assistants and 15 special lecturers, a total of 51. The college expects to equip its own hospital and polyclinic. The minimum requirements for admission are to be a full four years' high school course or its equivalent. The work covers a graded course of four years of nine months each. The first two years are to be given at Indiana University, Bloomington, while the junior and senior years are to be given at the College building, in Indianapolis, and will consist mainly of clinical instruction. The Dean is Dr. Allison Maxwell, and the Secretary is Dr. John F. Barnhill.

Bloomington.

INDIANA UNIVERSITY SCHOOL OF MEDICINE.—This school was organized in 1903, and gives the first two years of the regular four years' medical course. The year is nine months long. Two years of specified collegiate work in sciences and languages are required for entrance. The members of the faculty give their entire time to the teaching and investigation of their respective subjects. All the work of the school is university in character. The laboratory equipment is the best obtainable. The school is a member of the Association of American Medical Colleges. The faculty consists of 9 professors and 7 assistants, a total of 16. President W. L. Bryan is the Acting Dean. Dr. B. D. Myers, Secretary. The enrolment in 1905 6 was 21. The next session begins Sept. 18, 1906, and ends June 14, 1907.

IOWA.

Iowa, population 2,231,853, has five medical colleges The College of Medicine of the State University of Iowa and the College of Homeopathic Medicine of the State University of Iowa are located in Iowa City, population 7,987. In Des Moines, population 62,139, is the College of Medicine of Drake University. In Sioux City, population 31,701, is the Sioux City College of Medicine. In Keokuk, population 14,803, is Keokuk Medical College, College of Physicians and Surgeons. Board and lodging may be had in Des Moines for $15 a month and upward and in the other cities named for from $2.50 to $5 per week.

Des Moines.

DRAKE UNIVERSITY COLLEGE OF MEDICINE.—This school was organized in 1882 under the name of the Iowa College of Physicians and Surgeons. In 1900 it became affiliated with Drake University. The faculty consists of 20 professors and 30 assistants, a total of 50. The Mercy and Methodist hospitals, 200 beds, and a large dispensary clinic furnish clinical material. The college is a member of the Association of American Medical Colleges. The requirements for admission, after the 1st of July, 1905, will be a full four years' high school course or its equivalent. The work covers a graded course of four years of nine months each. The total fees for the first two years are $107 each, including laboratory and dissecting material; for the last two years, $89 each, including hospital fees. The Dean is Dr. D. S. Fairchild. The total registration for 1905-6 was 81; graduates, 10. The next session begins Sept. 17, 1906, and ends June 13, 1907.

Iowa City.

COLLEGE OF MEDICINE OF THE STATE UNIVERSITY OF IOWA.—This department was organized in 1870. The faculty is made up of 10 professors, 18 lecturers, demonstrators and assistants, a total of 28. The University Hospital, built in 1897 at a cost of $50,000, supplies the clinical material. The school is a member of the Association of American Medical Colleges. The course of study covers four years of thirty-six weeks each, embracing graded laboratory, didactic and clinical work. New laboratories have been erected, histology, embryology, anatomy, physiology, pharmacology, pathology, bacteriology and clinical medicine. Combined courses leading to more than one degree are offered. Total fees for each year are $50. The Dean is Dr. James R. Guthrie, Dubuque; Vice-Dean, Dr. Walter L. Bierring, Iowa City. Total number of students registered for 1905-6 was 267; graduates, 50. The thirty-seventh session opens Sept. 18, 1906, and ends June 12, 1907.

College of Homeopathic Medicine of the State University of Iowa.—This was organized in 1877. The faculty is composed of 12 professors and 12 lecturers and assistants, a total of 24, but some of these are of the faculty of the College of Medicine. The requirements for admission and the work, with the exception of that pertaining to homeopathy, are the same as those for the College of Medicine of the State University of Iowa. The fees are also the same. The Dean is Dr. George Royal, Des Moines. Total registration for 1905-6 was 47; graduates, 8. The thirtieth session begins Sept. 18, 1906, and will end June 12, 1907.

Keokuk.

Keokuk Medical College, College of Physicians and Surgeons.—In 1849 the College of Physicians and Surgeons, Keokuk, was organized, and four years later it became the Medical Department of the University of Iowa, continuing as such until 1870, when the original name was resumed. By the union in 1899 of this college with the Keokuk Medical College, organized in 1890, the present school under the above name was founded. The clinical material is good. St. Joseph's Hospital, having 100 beds and a splendid equipment, is open to the student for study and the clinics held there are large and varied. The faculty is composed of 21 professors and 7 assistants and demonstrators, 28 in all. This college is a member of the Association of American Medical Colleges. The studies embrace a graded course of four years of eight months each. The total fees for the first year are $66; for the second, $61; for the third, $64, and $61 for the last year. The Secretary is Dr. C. E. Ruth. Total registration for 1905-6 was 170; graduates, 50. The next session begins Sept. 18, 1906, and ends May 14, 1907.

Sioux City.

Sioux City College of Medicine.—This school was organized in 1891. The faculty numbers 26. Clinical material is supplied by St. Joseph's Mercy and Samaritan Hospitals and a college dispensary. This college is a member of the Association of American Medical Colleges. The system of study embraces a four-year graded course, eight months being a school year. Final examinations are held at the close of each course of instruction. Matriculation fee, paid but once, $5; tuition, each year, $48; hospital fees, $5, and graduating fee, $20. The President is Dr. J. N. Warren. Total number of students registered, 1905-6, was 72; graduates, 14. The seventeenth sessions opens Sept. 13, 1906, and will close May 2, 1907.

KANSAS.

Population 1,600,000, has two medical colleges. Kansas Medical College is in Topeka, population 35,388, and the School of Medicine of the University of Kansas, giving its first two years in Lawrence, population 11,123, and the last two years in Rosedale, a suburb of the two Kansas Citys, population 250,000. Board and lodging in all these places may be had for $3 to $5 per week.

Lawrence and Kansas City.

University of Kansas School of Medicine.—Was organized in 1880. In 1899 the preclinical course of two years was established. In 1905 it merged with three Kansas City schools, viz., the Kansas City Medical College, founded in 1869; the College of Physicians and Surgeons, founded in 1893, and the Medico-Chirurgical College, founded in 1896. This school is a member of the Association of American Medical Colleges. The faculty, including lecturers and clinical assistants, numbers 117. Each yearly term is thirty-six weeks in length, dividing into two semesters. The laboratories in Lawrence are extensive and well equipped. In Rosedale the laboratory for chemical pathology is a brick-and-stone structure, 50x100 feet, of three stories; besides this, the school has three dispensaries, the beginnings of a hospital of its own and the use of one public and three private hospitals. Of the faculty named above, nineteen are on salary. A combined course of six years is offered, conferring, after six years, the degrees of A.B. and M.D. The total fees are, for the first two years, $60 per year (and for non-residents of the state $70); for the last two years, $100 per year. The Dean at Lawrence is Dr. Merwin T. Sudler. The Dean of the clinical department at Kansas City is Dr. George Howard Hoxie. The number of students registered for 1905-6 was 150; graduates, 57. The next session begins Sept. 12, 1906, and will end June 5, 1907.

Topeka.

Kansas Medical College, Medical Department of Washburn College.—This college, organized in 1890, has a faculty of 28 professors and 12 lecturers and assistants, 40 in all. Good material for both medical and surgical clinics is found in Chirst's Hospital, with 100 beds, and Topeka State Hospital; the dispensary, in the college building also supplies material for class demonstration. The college is a member of the Association of American Medical Colleges. The college building affords ample laboratory and lecture-room space. The course of study is a graded one, covering four years of thirty weeks each. Individual instruction is especially aimed at. The total fees are $70 each year. The Dean is Dr. William S. Lindsay; Secretary, Dr. William McVey. The total registration for 1905-6 was 90; graduates, 18. The seventeenth session begins Sept. 4, 1906, and will close April 17, 1907.

KENTUCKY.

Kentucky, population 2,147,174, has seven medical colleges. They are all situated in Louisville, a city of 215,945 inhabitants, and are as follows: University of Louisville Medical Department, Kentucky School of Medicine, Louisville Medical College, Hospital College of Medicine, Southwestern Homeopathic Medical College, Kentucky University Medical Department and the Louisville National Medical College. Board and lodging in Louisville cost from $3 to $4 per week.

Louisville.

Kentucky School of Medicine.—This school was organized in 1850 and has a faculty composed of 20 professors, 27 lecturers, instructors and assistants, a total of 47. It is a lineal descendant of the Medical Department of Transylvania University, then situated at Lexington, Ky. The College Hospital, City Hospital and the college dispensary furnish the facilities for clinical study. The student is brought directly into contact with the patient through dispensary and bedside work by dividing the classes into sections. This college is a member of the Association of American Medical Colleges. The laboratories and their equipment are good. The curriculum embraces a four years' course of 28 weeks each. The fees for the first three years are $75 each; for the four year, $100. The Dean is Dr. W. H. Wathen, 628½ Fourth Avenue. Total number of students registered for 1905-6 was 275; graduates, 48. The next session begins Dec. 15, 1906, and will end July 12, 1907.

Louisville Medical College.—This school was organized in 1869 and has a faculty of 12 professors and 18 instructors and assistants, 30 in all. The City Hospital, College Infirmary and a dispensary offer good clinical facilities. Applicants for admission must show by diploma, certificate or examination that they are sufficiently proficient in English, arithmetic, algebra, physics and such Latin as would be acquired in one year's study. The laboratories and lecture rooms are ample. The course of study covers four years of six months each. The fees are $75 each year, with graduating fee of $25. The Secretary is Dr. Irvin Abell. Total registration for 1905-6 was 216; graduates, 54. The next session opens Dec. 11, 1906, and closes July 1, 1907.

Hospital College of Medicine.—This school is the medical department of Central University of Kentucky and was organized in 1873. The faculty is composed of 16 professors and 35 assistants, lecturers, etc., a total of 51. The Gray Street Infirmary, City Hospital and a well-equipped college dispensary present good facilities for clinical study. This college is a member of the Association of American Medical Colleges. Laboratory work, which is a prominent feature of the course, is thorough and practical. The laboratories and amphitheaters are ample in equipment and capacity, and the hospital advantages give opportunity for personal bedside instruction. The course covers four years of seven months each. Total fees for each of first three years, $75, and $100 for the fourth year. The Dean is Dr. P. Richard Taylor. Total enrolment for 1905-6 was 338; graduates, 94. The thirty-third session opens Dec. 1, 1906, and closes July 1, 1907.

Kentucky University Medical Department.—This school was reorganized in 1898. The faculty is composed of 17 professors and 25 lecturers, demonstrators, etc., 42 in all. Broadway Infirmary, the City Hospital and the college dispensary furnish clinical material. The school is a member of the Association of American Medical Colleges. The buildings provide ample facilities for clinical, laboratory and didactic instruction. The course of study embraces graded work for four years of thirty weeks each. Tuition is $75 per session and $25 graduation fees. The Dean is Dr. Thomas C. Evans, 654 Fourth Ave. Total number of students registered in 1905-6 was 284; graduates, 82. The next session begins Jan. 1, 1907, and ends July 31, 1907.

University of Louisville Medical Department.—This school was organized in 1837 under the name Louisville Medical Institute, and in 1846 assumed its present title. It has a faculty of 12 professors and 22 lecturers, demonstrators, etc., a total of 34. The University Hospital, City Hospital, Sts. Mary and Elizabeth Hospital, together with the college dispensary, furnish good clinical material. The course covers graded work for four years of seven months each. Total fees: First three years, $75 each, and fourth, $100. The Dean is Dr. J. M. Bodine. Total registration for 1905-6 was 213; graduates, 47. The seventieth session begins Oct. 1, 1906, and ends May 1, 1907.

Louisville National Medical College.—Colored. This was chartered in 1888 and shows a teaching force of 25. There is a four-year course, seven months to the year; the fees are $58, $58, $55 and $50 for the four years respectively. The Dean is Dr. E. S. Porter, Tenth and Walnut. The attendance, 1905-6, was 50; graduates, 7. The next session opens Oct. 2, 1906, and ends May 17, 1907.

Southwestern Homeopathic Medical College.—This college was organized in 1892 and has a faculty of 17 professors and 10 lecturers and assistants, 27 in all. A college dispensary supplies clinical material. The curriculum covers four years of seven months each. Total fees: First and second years, $80; third, $70, and $65 for the fourth. The Dean is Dr. A. L. Monroe. Total number of students for 1905-6 was 16; graduates, 6. Next session opens Sept. 26, 1906, and closes April 24, 1907.

LOUISIANA.

Louisiana, having a population of 1,381,625, contains two medical colleges: Medical Department of the Tulane University of Louisiana and New Orleans University. They are both situated in New Orleans, a city of 300,625 people. The cost of room and board is from $16 to $22 a month.

New Orleans.

Medical Department of the Tulane University of Louisiana.—This school was organized in 1834 as the Medical College of Louisiana, and became by law, in 1847, the Medical Department of the University of Louisiana, and in 1884 the Medical Department of the Tulane University of Louisiana. The faculty and all other instructors number over 50. By acts of legislature the Charity Hospital, with 900 beds, has been opened to the students of this school for clinical study, not only in medicine and surgery, but also in obstetrics and gynecology. In the year 1905 there were 9,074 cases treated in the wards of this hospital; these were indoor patients; and in addition 19,429 outdoor patients were treated in the free dispensary department. The Milliken Memorial Hospital, with a capacity for 200 children, is also available for study of clinical cases. Bedside instruction is given by the attending physicians to these hospitals, and postmortem examinations are held before the students. The laboratories are large and well equipped, and the lecture rooms and recitation rooms are ample. The course of study covers four terms of twenty-eight weeks each. Total fees for the first two years are $135 each and for the third and fourth $145 and $170 respectively. The Dean is Dr. Stanford E. Chaille, P. O. Drawer 261. The total number of students registered for 1905-6 was 458; graduates, 102. The seventy-third session begins Oct. 8, 1906, and will close May 8, 1907.

Flint Medical College of New Orleans University.—Colored. This school was organized in 1889 as the Medical College of New Orleans University. Name changed to the above in 1901. The faculty is made up of 10 professors, 6 lecturers and instructors, 16 in all. Four of the professors devote all their time to teaching and research. Clinical material is supplied by the Sarah Goodridge Hospital and by an outdoor clinic. This college is a member of the Association of American Medical Colleges. The curriculum covers a graded course of four years, twenty-six weeks each. The laboratories and lecture rooms are ample. Examinations are held monthly. Total fees, $50 each year. The Dean is Dr. A. D. Bush, 1566 Canal St. Total enrolment for 1905-6 was 54; graduates, 8. The seventeenth college year begins Oct. 1, 1906, and will end April 15, 1907.

MAINE.

Maine, population 694,466, has one medical college, located in Portland, population 52,656. Board and lodging cost from $3 to $5 a week.

Portland.

Medical School of Maine.—This, the Medical Department of Bowdoin College, was organized in 1820. It has 16 professors and 19 instructors, total 35. Students of the first and second years are instructed in Brunswick, a town of 6,800 inhabitants. The third and fourth year classes are taught in Portland, where are situated the Maine General Hospital and other clinical advantages. Applicants for admission, unless they possess diplomas, are examined in English, arithmetic, algebra, geometry, United States History, physics, chemistry and Latin. The course covers four years of eight months each. The total fees are $120 for the first year; for the second and third, $110, and $110 for the fourth year. The Dean is Dr. Alfred Mitchell, Brunswick. Total number of students in 1905-6 was 82; graduates, 17. The next session opens Oct. 25, 1906, and closes June 26, 1907.

MARYLAND.

Maryland, with a population of 1,188,044, contains eight medical colleges, all located in Baltimore, a city with 531,313 inhabitants. They are as follows: School of Medicine of the University of Maryland, College of Physicians and Surgeons, Baltimore University School of Medicine, Baltimore Medical College, Women's Medical College, Southern Homeopathic Medical College, Johns Hopkins Medical School and Maryland Medical College. The Bay View Hospital, having a capacity for 2,000 patients, is open to students for clinical instruction and furnishes good opportunities for practical demonstration. Board and lodging can be obtained for from $3 to $5 per week.

Baltimore.

Johns Hopkins Medical School.—This is the Medical Department of Johns Hopkins University, and was organized in 1893. The faculty comprises 11 professors, 71 lecturers, clinical professors, associate professors, associates, instructors and assistants, a total of 82. The Johns Hopkins Hospital and Dispensary furnishes abundant and varied clinical material; the lying-in department of the hospital, opened in 1896, is in successful operation. The requirements for admission demand that the applicant either has (*a*) completed the chemical-biologic course which leads to the A.B. degrees in the university; (*b*) graduated at an approved college or scientific school and can furnish evidence of an acquaintance with Latin and a fair reading knowledge of French and German, and a knowledge of physics, chemistry and biology, such as may be obtained from a year's course, including laboratory instruction. The school is a member of the Association of American Medical Colleges. The laboratories are large, well lighted and well equipped. The buildings are ample and built expressly for the purpose for which they are used. In the method of instruction special emphasis is laid on practical work in the laboratories, dispensary and wards of the hospital. The first two years are devoted mainly to practical work in the laboratories, combined with demonstrations, recitations and lectures, and during the remainder of the course opportunity for the personal study of cases is given. The work covers a graded course of four years, eight and a half months to the year. Final examinations, partly written and partly oral, include practical tests in laboratory and clinical work; the general character of the student's work is closely watched. The charge for tuition is $200 per annum, with no fees unless a microscope is rented; that fee is $5 a year. The Dean is Dr. William H. Howell, 232 West Lanvale St. Total registration in 1905-6 was 293; graduates, 84. The next session begins Oct. 3, 1906, and ends June 2, 1907.

University of Maryland School of Medicine.—This institution was organized in 1807 as the *College of Medicine of Maryland*, and in 1812, other faculties having been added, the whole was chartered under the name of the University of Maryland. The faculty is composed of 14 professors, 46 associates and lecturers, etc., a total of 60. The University Hospital, a part of which is used for a hospital for foreign seamen and another portion for a free city hospital, offers excellent clinical facilities. Besides this, the Presbyterian Eye, Ear and Throat Charity Hospital, in which 11,844 patients were treated in 1905; the Hospital for the relief of Crippled and Deformed Children, containing 40 beds; the Maternity Hospital and a college dispensary furnish material for clinical study. This school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are ample and well equipped. An entirely new laboratory building has just been erected. The fourth-year class, divided into sections, receives special training in practical laboratory work in a well-appointed clinical laboratory. Didactic, laboratory and clinical instruction, special attention being paid to bedside work, make up the system of teaching. The course covers four years of eight months each, and is graded. The total fees for the first two years are $135 each; for the third year, $125, and $155 for the final year. The Dean is Dr. R. Dorsey Coale. The total number of students registered in 1905-6 was 339; graduates, 83. The one hundreth session begins Oct. 1, 1906, and will terminate June 1, 1907.

Baltimore Medical College.—This college was organized in 1881 and has a faculty of 59. The clinical material is furnished by the Maryland General Hospital, having a capacity of 200 beds; the Maryland Lying-in Hospital; the Mount Hope Retreat, which presents good opportunity for the study of nervous and mental diseases, and a college dispensary, which, beside the great number of ambulatory patients treated, has an outdoor department that permits of the advanced student taking care of charity cases and carrying out his own treatment. This college belongs to the Association of American Medical Colleges. The college buildings afford ample laboratory, clinical and lecture-room space. Bedside teaching in the hospital wards is carried on in sections, and every member of the senior class is required to attend throughout the session. The course of study is graded and covers four years of eight months each. The Dean is Dr. David Streett. The total number of students registered in 1905-6 was 441; graduates, 97. The twenty-sixth session opens Sept. 20, 1906, and closes May 20, 1907.

College of Physicians and Surgeons.—This school was organized in 1872, and in 1878 Washington University School of Medicine, established in 1827, was consolidated with it. The faculty numbers 53. The clinical facilities, beside those afforded in common with other schools, are supplied by the Baltimore City Hospital, containing 225 beds; the Hospital for the Colored Race, containing 100 beds; the Nursery and Child's Hospital, with 150 beds; the Maryland Lying-in Asylum and a college dispensary. This school is a member of the Association of American Medical Colleges. The work covers a graded course of four years, eight months constituting a year. Total fees are $115, $115, $115 and $135 for the respective years. The Dean is Dr. Charles F. Bevan. The total number of students registered in 1905-6 was 291; graduates, 65. The next session opens Oct. 1, 1906, and closes June 1, 1907.

Maryland Medical College.—This school was organized in 1898 and has a faculty of 19 professors, 25 associates, lecturers, etc., 44 in all. The Franklin Square Hospital, West End Maternite and a college dispensary furnish clinical material. The course of study covers four years of nine months each. A matriculation fee of $5 and total laboratory fees for the four years of $55 are charged; tuition is $75 each year. The Dean is Dr. J. B. Schwatka, 1003 North Broadway. Total registration for 1905-6 was 124; graduates, 29. The ninth session begins Sept. 15, 1906, and closes May 3, 1907.

Woman's Medical College.—This school was organized in 1882 and has a faculty of 17 professors, 15 associates, assistants and lecturers, a total of 32. The Hospital of the Woman's Medical College and a college dispensary furnish general clinical material, while abundant special material is furnished by the Presbyterian, Eye and Ear and the Sheppard and Enoch Pratt (for mental cases) Hospitals. The college is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are equipped with all necessary apparatus; the practical work is emphasized. Eight months constitute a school year and the course covers graded work for four years. The total fees for the first three years are $106 each and $81 for the last year, with $30 graduation fee. The Dean is Dr. S. Griffith Davis, 1230 Light St. Total number registered for 1905-6 was 33; graduates, 3. The twenty-fifth session opens Oct. 1, 1906, and closes May 31, 1907.

Southern Homeopathic Medical College.—This school was organized in 1890, with a faculty of 10 professors and 14 associates and lecturers, a total of 24. It now has a faculty, including professors, associates, lecturers and demonstrators, consisting of 37 in all. The clinical facilities are those offered by the Maryland Homeopathic Hospital and St. Luke's Hospital, which together have about 75 beds. There is also a polyclinic dispensary in the basement of the college building, which furnishes considerable lecture material; the obstetric department of the Maryland Homeopathic Hospital also furnishes clinical material. One of the features of the institution is the outdoor work done by the students, including a large amount of obstetric work. Applicants for matriculation must pass a satisfactory examination in English, arithmetic, geography, history and Latin, unless they possess satisfactory evidence that they have done a corresponding amount of work. The course covers graded work for four years of seven months each. The fees are $80 for the first year, $75 each for the second and third and $105 for the fourth year. The Dean is Dr. Eldridge C. Price. 1012 Madison Ave., and the Registrar is Dr. L. R. Palmer, 1021 Madison Ave. Total registration for 1905-6 was 18; graduates, 5. The sixteenth session begins Oct. 3, 1906, ends May 2, 1907.

Baltimore University School of Medicine.—This school, organized in 1884, has a faculty of 8 professors and 16 lecturers, demonstrators, etc., in all 24. The Baltimore University Hospital, Lying-in Hospital and the clinical material used in common with the other schools supply the facilities for practical work. The course is four years of nine months each. The fees are about $100 each year. The Dean is Dr. Hampson H. Biedler, 119 W. Saratoga St. Total registration for 1905-6 was 18; graduates, 7. The next session opens Sept. 6, 1906, and closes June 1, 1907.

MASSACHUSETTS.

Massachusetts, population 2,805,340, has four medical colleges: Medical School for Harvard University, Boston University School of Medicine, College of Physicians and Surgeons and Tufts College Medical School. They are all situated in Boston, a city of 594,618 inhabitants. Board and lodging can be obtained from $5 to $7 per week.

Boston.

Medical School of Harvard University.—This was organized in 1782 and has a faculty of 32 professors, 113 associates and assistants, etc., a total of 145. Beside the clinical advantages mentioned, the Boston Lyin-in Hospital, the Boston Dispensary, where 43,918 patients were treated last year; the Infants' Hospital, the Children's Hospital, Long Island Hospital, containing 250 beds, and the Marine Hospital all furnish excellent opportunity to the student for clinical study. Students are also permitted to visit the Free Hospital for Women and Carney Hospital on application to the physicians on duty. Candidates for admission "must present a degree in arts, literature, philosophy or science from a recognized college or scientific school, with the exception of such persons, of suitable age and attainments, as may be admitted by special vote of the faculty in each case. Each candidate is required to hand in the original note book in which he recorded the work performed by him in qualitative analysis, and also to pass a written examination in theoretical and descriptive chemistry. If conditioned in chemistry one year is allowed in which to remove the condition. The laboratories and lecture rooms offer ample facilities and the equipment is good; special facilities are open to those desiring to pursue advanced or original work. The course of study covers four years of nine months each; the course is graded and each corelated group as taken up presents sufficient variety to avoid monotony. A series of written, oral and practical examinations are distributed throughout the course of study. Fees: Matriculation, $5; $200 each year. The Dean is Dr. William L. Richardson, 688 Boylston St. The total registration for 1905-6 was 292; graduates, 66. The 125th session begins Sept. 27, 1906, and ends June 26, 1907.

Tufts College Medical School.—This school was organized in 1893 as the Medical Department of Tufts College. It has a faculty of 30 professors, 55 assistants and lecturers, etc., a total of 85. Clinical material is furnished by the Boston City Hospital, Massachusetts Charitable Eye and Ear Infirmary, Free Home for Consumptives, Free Hospital for Women, Boston Dispensary, Cambridge Hospital, St. Elizabeth's Hospital, Carney Hospital and the college dispensary; the student has also the advantages derived from an out-department in connection with the Boston Dispensary. "Graduates of an approved high school, college or university and students having certificates of entrance to a college or university, or holding the State of New York Regents' certificate," also certain approved preparatory school graduates, are admitted without examination; all others must pass an examination in English, Latin, physics and mathematics, including elementary algebra and plane geometry, besides one elective subject to be chosen from American history, French, German, chemistry or biology. The laboratories and lecture rooms are ample in their equipment and capacity. Teaching is carried on by means of lectures, recitations and practical work in the laboratories and clinics; frequent examinations are held during a course and final examination on completing the subject. Graded instruction covering four years of eight months each makes up the full course. The total fees are $150 each year; dissecting material is furnished at cost. The Dean is Dr. Harold Williams. Total number of students for 1905-6 was 375; graduates, 73. The thirteenth session begins Sept. 26, 1906, and ends June 1, 1907.

College of Physicians and Surgeons.—This school was organized in 1880 and has a faculty of 27 professors and 18 lecturers and assistants, a total of 45. Clinical facilities are furnished by the North End Dispensary Hospital, Union General Hospital and the city and state institutions. This school is a member of the Association of American Medical Colleges. The course of study covers graded work for four years of nine months each. The total fees for the first year are $100 and for each of the other years about $110, with a graduation fee of $30. The Dean is Dr. C. H. Cobb, Hotel Oxford, Boston, and the Registrar is Dr. John H. Jackson, 155 Franklin St., Fall River. Total students registered 1905-6, 134; graduates, 20. The twenty-seventh session begins Sept. 19, 1906, and ends June 21, 1907.

Boston University School of Medicine.—Homeopathic. This school was organized in 1873. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The faculty includes 23 professors, 36 associates and assistants, etc., a total of 59. Clinical material is furnished by the Massachusetts Homeopathic Hospital, containing 235 beds, an out-patient department, a maternity hospital and the Westborough Insane Hospital, 800 patients. Candidates who have taken their degrees in arts, philosophy or science are not examined; certificates of graduation from approved high and preparatory schools accepted in lieu of entrance examinations; all others are examined in English, Latin, French or German, history, mathematics, physics and chemistry. The instruction is graded and covers a period of four years, eight months each. Total fees for the first year are $105; for the second and third, $125 each, and for the last year $155. The Dean is Dr. John P. Sutherland, 302 Beacon St. Total registration for 1905-6 was 100; graduates, 23. The thirty-fourth session opens Oct. 4, 1906, and closes June 5, 1907.

MICHIGAN.

Michigan, population 2,420,982, has six medical colleges. Two of these, University of Michigan Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a city of 16,033 people. Board and lodging cost from $2.50 to $5 a week. Detroit, a city of 309,653 inhabitants, contains three medical colleges, as follows: Detroit College of Medicine, Detroit Homeopathic College and the Michigan College of Medicine and Surgery. Board and room can be obtained for $3 a week and upward. Grand Rapids Medical College is located in Grand Rapids, population 91,630. Room and board cost from $3 to $3.50 a week.

Ann Arbor.

University of Michigan Department of Medicine and Surgery.—This was organized in 1850 and has a faculty composed of 19 professors, 40 associates, instructors, etc., a total of 59. The University Hospital, with nearly 200 beds, furnishes the clinical facilities. The requirements for admission provide that the applicant, either by certificate or examination, show a sufficient knowledge of the following: English grammar, rhetoric and composition; United States and general history; algebra, through quadratics, plane and solid geometry and plane trigonometry; physics, biology and chemistry, these subjects to be accompanied by laboratory work; German or French and Latin. The laboratories and their equipment are good and the training in them and in didactic work is thorough. The new medical building, accommodating the laboratories of hygiene, bacteriology, physiologic chemistry, pathology, histology, embryology and anatomy, is now completed and occupied. This school is a member of the Association of American Medical Colleges. The curriculum embraces four years of nine months each. A combined course leading to degrees in both arts and medicine in six years is offered. The total fees for Michigan students for the entire course of four years is about $300, and for others $350. The Dean is Dr. Victor C. Vaughan. Total registration for 1905-6 was 442; graduates, 70. Next session begins Sept. 25, 1906, and will end June 20, 1907.

Homeopathic College, University of Michigan.—This department of the university was organized in 1875 and has a faculty of 29 professors and 21 assistants, total 50; a part of the teaching force is from the other departments of the university. The Homeopathic Hospital, containing 140 beds, furnishes material for clinical teaching. The course covers four years of nine months each. The total fees for Michigan students are about $240 for the four years, and for other students about $295. The Dean is Dr. W. B. Hinsdale. The enrolment for 1905-6 was 80; graduates, 17. The next session begins Sept. 25, 1906, and closes June 20, 1907.

Detroit.

Detroit College of Medicine.—This school was formed in 1885 by the union of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, established 1880. The faculty embraces 21 professors, 71 lecturers, instructors, etc., a total of 92. Clinical facilities are offered by the following hospitals: St. Mary's and Harper, each of which contains a free dispensary; Woman's St. Luke's, the Children's Free Hospital and the House of Providence. This school is a member of the Association of American Medical Colleges. The course covers four years of eight months each. The work includes laboratory, didactic and clinical study. Fees: Matriculation, paid once, $5; tuition, each term, $65; hospital and laboratory tickets, each $10, and diploma fee, $30. The Secretary is Dr. H. O. Walker. Total enrolment for 1905-6 was 173; graduates, 82. The next session begins Sept. 19, 1906, and will close May 30, 1907.

Michigan College of Medicine and Surgery—Saginaw Valley Medical College.—These two schools, organized in 1888 and 1896 respectively, were consolidated last year, to continue on the site of the former. The faculty numbers 51. Clinical facilities are offered by a college dispensary, the Emergency Hospital and Detroit Eye and Ear Infirmary. This school is a member of the Association of American Medical Colleges. The course covers graded work for four years of eight months each. The fees are about $80 to $95 per year; third year, $70, and $95 for the fourth year. The Dean is Dr. Hal. C. Wyman, 46 West Adams Ave. Total registration for 1905-6 was 68; graduates, 22. The next session begins Sept. 18, 1906, and will end May 17, 1907.

Detroit Homeopathic College.—This was organized in 1899 and has a faculty of 36. Grace Hospital and a college dispensary are available for study of clinical cases. Unless possessing at least a high school diploma applicants for admission will be examined by the state board. The course embraces work for four years of eight months each. Fees: From $70 to $90 per year. The Dean is Dr. D. A. MacLachlan; Registrar, J. M. Griffin. Total enrolment for 1905-6 was 33; graduates, 15. The next session begins Sept. 15, 1906, and will close May 15, 1907.

Grand Rapids.

Grand Rapids Medical College.—This was organized in 1897. The faculty is made up of 27 professors and 6 assistants, in all 33. Clinical cases in the Union Benevolent Association, St. Mary's and Woman's hospitals and St. John's Orphan Asylum and a college dispensary are available for study. The course is four years of eight months each. The total fees are about $85 for each year. The Dean is Dr. G. L. McBride, 257 East Fulton St. Total registration for 1905-6 was 40; graduates, 12. The next session opens Sept. 12, 1906, and closes May 18, 1907.

MINNESOTA.

Minnesota, population 1,751,394, contains three medical colleges: Hamline University College of Medicine and the two medical departments of the University of Minnesota, viz., the College of Medicine and Surgery and the College of Homeopathic Medicine and Surgery. They are all situated in Minneapolis, which, together with St. Paul, which is in close proximity, has a population of 386,150. The various hospitals of Minneapolis and St. Paul furnish ample clinical material. The average cost of board and lodging is $20 a month.

Minneapolis.

College of Medicine and Surgery, University of Minnesota.—This department of the University of Minnesota was created in 1883, but at that time its only function was to examine for the degrees of B.M. or M.D. In 1888, by the consolidation and absorption of the Minnesota Hospital *Medical College and the* St. Paul Medical College, its present status was assumed. The faculty is composed of 30 professors and 75 instructors and assistants, a total of 105. The medical school occupies seven buildings, and its laboratories are excellent. Eight large hospitals in the Twin Cities, beside the university dispensary and St. Paul Dispensary, afford an abundant supply of material for clinical study. The curriculum covers four years of nine months each and the work is carefully graded. The entrance requirement of two years of university in addition to four years of high school work limits the number of students, but assures a high standard of the student body. This school is a member of the Association of American Medical Colleges. Total number of students registered in 1905-6 was 189; graduates, 43. Total fees for each year, $100. The Dean is Dr. F. F. Wesbrook. The next session opens Sept. 13, 1906, and closes June 9, 1907.

College of Homeopathic Medicine and Surgery.—This is a department of the University of Minnesota and was organized in 1888. The faculty comprises 19 professors and 14 assistants, 33 in all. Instruction in the primary branches is received, in common with the students of the College of Medicine and Surgery, from the professor of the department of medicine. The course is graded, extending over four years of nine months each. The total fees for the first two years are $100 each and $80 each for the last two years. The Dean is Dr. Eugene L. Mann. Total number of students registered in 1905-6 was 15; graduates, 1. The next session opens Sept. 13, 1906, and closes June 9, 1907.

Minneapolis College of Physicians and Surgeons.—Medical Department of Hamline University. This was organized in 1883. Its faculty is composed of 29 professors and 17 instructors, a total of 46. The laboratories and lecture rooms are large, well lighted and supplied with all the necessary equipment. Clinical work is offered to the student in City Hospital, Asbury Methodist Hospital, St. Barnabas and St. Mary's hospitals in Minneapolis, Luther Hospital, City and County and St. Joseph's in St. Paul and the college dispensary. This school belongs to the Association of American Medical Colleges. The course of study covers graded work for four years, eight and a half months making a year. Total fees, first year, $90· second year, $92.50, and for each of the last two $80. The Dean is Dr. George C. Barton. Total number of students, 1905-6, was 120; graduates, 27. The next session begins Sept. 18, 1906, and ends June 5, 1907.

MISSISSIPPI.

Mississippi, population 1,551,270, has two medical colleges: The Medical Department of the University of Mississippi, located at Oxford, a city of 2,000 inhabitants, and the Mississippi Medical College, at Meridian, with a population of 15,079.

Oxford.

University of Mississippi Medical Department.—This school was organized two years ago with 6 professors and 2 assistants, a total of 8. Each college term extends over nine months. Only two years of the medical course are given. The school is a member of the Association of American Medical Colleges. Dr. W. S. Leathers is the Acting Dean. The total registration in 1905-6 was 22: graduates, none. The next session begins Sept. 21, 1906, and ends June 7, 1907.

Meridian.

Mississippi Medical College.—Organized in 1906 with 15 professors and a corps of demonstrators. Buildings are in course of construction. The Dean is Dr. N. L. Clark. The first session will begin Oct. 1, 1906.

MISSOURI.

Missouri, population 3,106,665 has *eleven medical colleges.* St. Louis, population 612,279, contains six of these, viz., St. Louis College of Physicians and Surgeons, American Medical College, Homeopathic Medical College of Missouri, Medical Department St. Louis University (Marion-Sims-Beaumont College of Medicine), Washington University Medical Department and Barnes Medical College. Board and lodging can be procured for from $3.50 to $5 a week. Kansas City, with 173,064 inhabitants, has three *colleges, namely:* University Medical College, the Hahnemann Medical College of Kansas City and Eclectic Medical University. Room and board can be obtained in this city for from $3 to $5 a week. Ensworth-Central Medical College is located in St. Joseph, population 110,479. Board and room can be had for from $3.50 to $5 a week. Department of Medicine of the University of Missouri is at Columbia, a town of 5,651. Board and lodging can be obtained at Columbia for from $2 to $5 a week.

Columbia.

Department of Medicine of the University of Missouri.—This department was organized at Columbia in 1872. The faculty includes 11 professors, 19 assistant professors, lecturers, etc., a total of 30. Clinical facilities are supplied by the Parker Memorial State Hospital. A new $40,000 building for the medical laboratories has recently been completed and has excellent equipment. Special emphasis is laid on thorough training in the scientific branches which constitute the foundation of medicine. Four years' course, nine months each, carefully graded. The university offers also a combined course of six years, conferring degrees in both arts and medicine. The candidate for entrance must present, beside the diploma from a recognized four-year high school, credentials of college work as follows: English, 6 hours; German, 6 hours; general zoology, 6 hours; general physics, 6 hours; inorganic chemistry, 6 hours. This school is a member of the *Association of American* Medical Colleges. There is no charge for tuition, the only expenses being a library fee of $10 each year and small laboratory fees. The Dean is Dr. A. W. McAlester. Total registration of students for 1905-6 was 98; graduates, 8. The next session opens Sept. 18, 1906, and closes June 7, 1907.

Kansas City.

University Medical College.—This was organized in 1881 as the University of Kansas City Medical Department, and in 1888 was reorganized under its present name. Its faculty comprises 29 professors and 41 lecturers and assistants, a total of 70. Clinical material is furnished by the University Hospital, owned by the college, with 100 beds; the City Hospital, German Hospital, Home for the Aged, containing 147 beds; the Sisters' Hospital, Scarritt and St. Margaret's hospitals, the Children's Home, St. Joseph's Orphan Asylum and the college dispensary and obstetric department. Instruction is given by means of lectures, recitations, demonstrations and laboratory work and clinics. The school is a member of the Association of American Medical Colleges. The college building, which has recently been enlarged, furnishes ample accommodations for laboratories and lecture rooms. The course of study covers four years of thirty weeks each and the work is graded. The total fees for each of the first two years are $100; for the third, $80 and $100 for the fourth year. The Dean is Dr. Samuel C. James, Bryant Bldg. The total number of student registered in 1905-6 was 235; graduates,, 54. The twenty-fifth session begins Sept. 6, 1906, and ends April 24, 1907.

Kansas City Hahnemann Medical College.—This school was formed by the union of the Kansas City Homeopathic Medical College, organized in 1888, and the Kansas City University College of Homeopathic Medicine and Surgery. It has a faculty of 37. The City Hospital, Homeopathic Hospital, the Sanitarium, Scarritt, University, Women and Children's, German, Bethany and Children's hospitals are open to its students for clinical study. The college dispensary and clinics also supply clinical material. Applicants for admission must show by diploma, certificate or examination that they have a sufficient knowledge of English, arithmetic, geography, United States history and Latin equal to one year's work. The course covers four years of seven months each. The Dean is Dr. Frank Elliott, 1023 Grand Ave. Total registration for 1905-6 was 76; graduates, 21. The next session begins Sept. 12, 1906, and closes April 15, 1907.

Eclectic Medical University.—This was organized in 1898, and has 25 in its faculty. The curriculum covers four years of seven months each. Fees, about $70 each year, with a graduation fee of $15. The Dean is Dr. Theodore Doyle. Total number of students for 1905-6 was 46; graduates, 16. The ninth session begins Sept. 11, 1906, and ends March 29, 1907.

St. Joseph.

The Ensworth Central Medical College.—This college was organized in 1876 as the St. Joseph Hospital Medical College. In 1882 it merged with the College of Physicians and Surgeons to form the St. Joseph Medical College. In 1888 changed name to Ensworth Medical College. In 1905 merged with the Central Medical College, organized in 1894, to form the Ensworth-Central Medical College. The faculty is composed of 28 professors, 13 lecturers and assistants, 41 in all. The Ensworth Deaconess Hospital with 100 beds; St. Joseph's with 250 beds; City Hospital containing 40 beds; the State Hospital, No. 2, which is open to the students once a week, and a college dispensary furnish clinical material. Applicants for admission must show by certificate or diploma, or examination that they possess an education equal to that of a graduate from a high school. The building furnishes ample laboratory and lecture room facilities. The curriculum covers a graded course of four years of seven months each. The fees are $75 for each of the first three years; the fourth year, $95. The Secretary is Dr. T. E. Potter. Total enrolment for 1905-6, 149; graduates, 34. The next session opens Sept. 10, 1906, and will close about May 10, 1907.

St. Louis.

Washington University Medical Department.—This school was organized in 1891 from the St. Louis Medical College, which was founded in 1842. In 1899 the Missouri Medical College, organized in 1840, was added. The faculty comprises 39 professors, 35 lecturers and instructors, a total of 74. Clinical material is furnished by the St. Louis Mullanphy Hospital, Washington University Hospital and Dispensary, Washington University Lying-in Hospital, Bethesda Hospital and O'Fallon Dispensary. In addition to these, the City Hospital and Insane Asylum are used in common with the other schools. The Medical Department is a member of the Association of American Medical Colleges. The college buildings, of which there are two, furnish the best laboratory and lecture-room facilities. The course is four years of eight months each, and the system of study embraces laboratory, didactic and clinical teaching. The total fees for the first year are $126.25; second, $120.25; and for the third, $106.25, and fourth, $101.25. The Dean is Dr. Robt. Luedeking. Total registration of students for 1905-6 was 239; graduates, 55. The next session opens Sept. 28, 1906, and closes May 30, 1907.

St. Louis University Medical Department (Marion Sims-Beaumont College of Medicine).—The faculty is composed of 42 professors, 63 lecturers and assistants, a total of 105. Clinical facilities are offered by Alexian Brothers' Hospital, with 250 beds; Rebekah Hospital, having a capacity of 50 patients; Josephine Hospital, 50 beds; Mt. St. Rose Throat and Chest Hospital, 150 beds; St. John's Hospital, 125 beds· St. Ann's Lying-in Hospital, 200 beds; St. Mary's Infirmary, containing 150 beds; the City Hospital and Insane Asylum, each with a capacity of 600 patients. Grand Avenue Dispensary also furnishes good material for practical instruction. This school is a member of the Association of American Medical Colleges. The buildings afford ample laboratory and lecture-room space, and they are well equipped. The course of study embraces laboratory and clinical instruction, with recitations and lectures. The curriculum covers four years of seven months each. The total fees for the first year are $100; for the second, third and fourth, $95 each. The Secretary is Dr. H. W.

Loeb, 537 North Grand Ave. Total number of students registered for 1905-6 was 295; graduates, 116. The next session opens Oct. 1, 1906, and closes May 20, 1907.

St. Louis College of Physicians and Surgeons.—This school was organized in 1878, and has a faculty of 24 professors, 15 lecturers, instructors, etc., a total of 39. The resources for clinical instruction are Jefferson Hospital, which is open to students of this college only; City Hospital, with 600 beds; Female Hospital, having 250 beds; City Insane Asylum; City Poorhouse, and the college dispensary. This college is a member of the Association of American Medical Colleges. The laboratory and lecture-room space and the equipment are ample. The course of study covers four years of seven months each, and is graded. Total fees for the first year are $80; second and third, $75 each and $85 for the fourth year. The Dean is Dr. Waldo Briggs, 2600 Gamble St. Total number of students registered, 1905-6, was 278; graduates, 53. The next session begins Sept. 15, 1906, and ends May 1, 1907.

Barnes Medical College.—(Medical Department Barnes University.) This school was organized in 1892, and has a faculty of 37 professors and 25 lecturers and assistants, a total of 62. The clinical advantages are those offered by Centenary Hospital, with 150 beds; City Hospital, the college dispensary and the outdoor obstetrical department. The laboratories are well equipped and other facilities ample. The course of study includes graded work for four years of eight months each. The total fees for the first three years are $80 each year, and $90 for the fourth year. The Secretary is Dr. C. M. Ament, 1025 Missouri Trust Bldg. Total registration for 1905-6 was 385; graduates, 72. The next session opens Sept. 11, 1906, and closes May 10, 1907.

American Medical College.—Eclectic. This was organized in 1873, and has a faculty of 17 professors. St. Louis City Hospital and a college dispensary supply ample clinical material. The requirements for admission are those of the National Confederation of Eclectic Medical Colleges of which this college is a member. The course of study covers four years of seven months each. The total fees are: Tuition, $75 per year, dissecting material, $5 per year for four years, final examination and graduation fee $25. Total registration for 1905-6 was 63; graduates, 22. The Dean is Dr. M. M. Hamlin, 2906 Lawton Ave. The next session opens Sept. 17, 1906, and closes April 18, 1907.

Homeopathic Medical College of Missouri.—This was organized in 1857, and has a faculty of 26 professors and 6 assistants, total, 32. The curriculum covers four years of seven months each. Fees: First year, $80; second, $75, third, $60, and $75 for the fourth year. The Dean is Dr. L. C. McElwee, 1221 North Grand Ave. Total registration for 1905-6 was 46; graduates, 4. *The next course begins Sept. 10, 1906, and ends April 20, 1907.*

NEBRASKA.

Nebraska, population 1,066,300, has four medical colleges: The University of Nebraska College of Medicine and John A. Creighton Medical College of Omaha, population 113,361, and Lincoln Medical College, and the Nebraska College of Medicine at Lincoln, population 44,243. Board and lodging can be obtained for from $3 to $5 a week.

Lincoln and Omaha.

University of Nebraska College of Medicine.—This was organized in 1880 as the Omaha Medical College. In 1902 an affiliation was entered into with the University of Nebraska, the name being changed to the College of Medicine of the University of Nebraska. The first two years are given at Lincoln. The last two years are given only at Omaha. The faculty is composed of 26 professors and 34 lecturers and assistants, total 60. The Douglas County, Immanuel, Wise Memorial and Omaha Methodist hospitals, together with the college dispensary, furnish an abundance of material for clinical study and demonstration. The course consists of graded studies covering four years of eight months each. The method of instruction consists of didactic and clinical lectures, section clinics, demonstrations, recitations and laboratory work. The college building is well adapted to its purpose, the laboratories being well equipped and the lecture room commodious. The fees, including breakage deposits, are $90 for the first two years, and $100 for the last two years. The college is a member of the Association of American Medical Colleges. Total number of students enroled in 1905-6, 142; graduates, 7. The Secretary is Dr. Geo. H. Bicknell, Karboch Block, Omaha. The next annual session begins Sept. 20, 1906, and ends May 25, 1907.

Omaha.

John A. Creighton Medical College.—This school, organized in 1892, is the Medical Department of Creighton University, and has a faculty of 28 professors and 26 associates, lecturers and assistants, a total of 54. The clinical facilities are those of St. Joseph's Hospital, containing 300 beds and having a clinical amphitheater connected with it; St. Bernard's Hospital, with 256 beds; Omaha General Hospital, with 100 beds; Douglas County Hospital; Mercy Hospital, and the college dispensary. Clinical material is abundant and varied. The building, which was completed in 1898, contains excellent facilities for laboratory and lecture-room work, and the equipment is adequate. In the methods of instruction including clinical, didactic and laboratory work, special emphasis is laid on practical work. The school is a member of the Association of American Medical Colleges. The course of study embraces four years of eight months each. The total fees for the first two years are $90 each, and $85 for each of the last two years. The Dean is Dr. D. C. Bryant, McCague Bldg. Total number of students registered in 1905-6 was 172; graduates, 39. The fifteenth sessions begins Sept. 4, 1906, and ends May 4, 1907.

Lincoln.

Lincoln Medical College.—Eclectic. This was organized in 1889, and has a faculty of 22. The requirements for admission are those of the National Confederation of Eclectric Medical Colleges, of which this college is a member. The course of study covers four years of thirty weeks each. The total fees for the first year are $80; second, $75; third, $75, and $85 for the fourth year, or $250 for all four years together. The Secretary is Dr. Earl E. Boyd. Total number of students for 1905-6 was 71; graduates, 15. The next session begins Sept. 13, 1906, and ends April 27, 1907.

Nebraska College of Medicine.—This college was organized in 1905. Its faculty consists of 23 professors and 5 assistants, a total of 28. Its course covers four years of eight months each. The Dean is Dr. J. F. Stevens. Registration of students during 1905-6 was 10; no graduates. The second session begins Sept. 19, 1906, and ends June 1, 1907.

NEW HAMPSHIRE.

New Hampshire, population 411,588, contains one medical college, located in Hanover, population 1,884.

Hanover.

Dartmouth Medical School.—This is the Medical Department of Dartmouth College, and was organized in 1797. Its faculty is made up of 18 professors and 3 instructors, 21 in all. The Mary Hitchcock Memorial Hospital, a cottage hospital of 36 beds, supplies the clinical material. Applicants for admission must possess an education at least equivalent to graduation from a registered high school. The laboratories afford good facilities for work. The course covers four years of thirty-two weeks each. Fees: $100 each year. The Dean is Dr. William T. Smith. The total number of students registered for 1905-6 was 59; graduates, 10. The work for the first and second years begins with that of the academic department, commencing Sept. 20, 1906, and closing June 27, 1907; for the advanced classes it begins Aug. 15, 1906, and ends April 1, 1907.

NEW YORK.

New York State, population 7,268,894, has ten medical colleges. Seven of these, College of Physicians and Surgeons, Columbia University, Long Island College Hospital, New York Homeopathic Medical College and Hospital, New York Medical College and Hospital for Women, Eclectic Medical College of the City of New York, Cornell University Medical College and the University and Bellevue Hospital Medical College, are located in New York City, population 3,716,139. This city, with its hospitals and dispensaries, offers abundant clinical material. *Board and lodging can be obtained for from $5 to $7* a week.

Albany Medical College is in Albany, a city of 93,920 people, where board and room can be had for from $4 to $5 a week.

The University of Buffalo Medical Department is situated in Buffalo, population of 381,403. Here board and lodging can be obtained for from $3.50 to $5 per week.

The College of Medicine, Syracuse University, is in Syracuse, a city of 114,443 inhabitants. Board and lodging can be obtained for from $3.50 a week upward.

New York City.

College of Physicians and Surgeons.—This school was organized in 1807 and its present relation, that of Medical Department of Columbia University, was assumed in 1860. The faculty embraces 34 professors and 174 demonstrators, instructors, etc., a total of 208. The Vanderbilt Clinic, where 45,355 patients were treated during the year 1905, and which is equipped with all modern appliances for the study and treatment of disease, and Sloane Maternity Hospital, containing 124 beds, offer exclusive clinical advantages to students of this school. The college is strongly represented on the staffs of most of the general and special hospitals of New York. In them both required and optional practical instruction is given by clinical lectures, in the dispensaries, and at the bedside, all of which are prominent features of the curriculum. These hospitals are as follows: Roosevelt, Bellevue, New York, Presbyterian, St. Luke's, General Memorial, Hospital for the Ruptured and Crippled, St. Mary's Free Hospital for Children, Willard Parker, Scarlet Fever and Reception, Riverside, New York Eye and Ear Infirmary, foundling, and the Babies' Hospital. The laboratories, lecture rooms and amphitheaters are ample in equipment and accommodation; special provisions are made to equip each student thoroughly in each of the laboratories and thus make the work individual. The work is graded, covering four years of eight months each. The Dean is Dr. Samuel W. Lambert. The total fees for the first year are $255; for the second and third, $250 and $275 for the fourth year. Total registration for 1905-6 was 450; graduates, 152. The next session begins Sept. 26, 1906, and ends June 12, 1907.

Long Island College Hospital.—This was organized in 1858 and has a faculty of 20 professors and 75 assistants, instructors, etc., a total of 95. Long Island College Hospital, containing 300 beds and connected with a four-story maternity hospital; Polhemus Memorial Clinic, Dudley Memorial and Hoagland Laboratory, completely equipped with the most modern apparatus, are all a part of the college. Beside the clinical facilities furnished by these, members of the faculty attend at Kings County, St. John's, Brooklyn, Norwegian, Williamsburg, Methodist Episcopal and the Brooklyn Eye and Ear hospitals, where the students are offered opportunities for clinical study. Many of these also contain outpatient departments, thus permitting advanced students to attend personally to cases. Bedside instruction is also given in the wards. The course covers four years of thirty weeks each. Fees: First year, $195; second, $200; third, $160, and $195 for the fourth year. The Secretary is Dr. Joseph H. Raymond. Total registration, 1905-6, was 343; graduates, 72. The forty-ninth session opens Oct. 1, 1906, and closes June 6, 1907.

Cornell University Medical College.—This department of Cornell University was established in 1898. The faculty is composed of 45 professors and 162 instructors and assistants, a total of 207. The City Hospital, having 1,000 beds; Bellevue Hospital, New York Hospital, Presbyterian, Willard Parker and Reception with 200 beds; New York Skin and Cancer; St. Francis, having a capacity of 230 beds; St. Vincent's, with 200 beds; the Manhattan Eye and Ear Infirmary, in addition to a large college dispensary, furnish the clinical resources; the material is abundant and varied. The first two years of the course are taken at New York or at Ithaca, and the work is devoted to the fundamental scientific subjects. The last two years are spent mostly in practical and clinical work and the hospital advantages are utilized. The Loomis Laboratory, a five-story modern building, is well equipped and supplies ample practical laboratory facilities required in the advanced work. "The essential features of the entire system is the division of the classes of the several years into small sections." Fees: First year, $190; second and third, $185 each, and $200 for the fourth year. The Dean is Dr. William M. Polk. Total registration for 1905-6 was 369; graduates. 59. The next session opens Sept. 26, 1906, and closes June 12, 1907.

University and Bellevue Hospital Medical College.—This is a department of the New York University, and was founded in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. The faculty is composed of 39 professors and 64 instructors, assistants, etc., in all 103. Bellevue and City Hospitals, hospitals of the workhouse and almshouse, Manhattan State Hospital for the Insane, Willard Parker and Reception hospitals, Riverside Hospital for Contagious Diseases, Randall's Island, Presbyterian, St. Luke's, St. Vincent's. General Memorial, Gouverneur, Columbus, Harlem, New York Foundling and the Society for the Lying-in hospitals, the New York Eye and Ear Infirmary and a large college dispensary are open to students of this school for a study of clinical cases. The Carnegie building, a five-story structure adjoining the college, is devoted to laboratory instruction and investigation, and, with the other two large college buildings, affords good laboratory and lecture-room facilities. A new six-story addition to the laboratory building has just been completed. The course of instruction covers four year sof eight months each. Actual clinical teaching, in conjunction with and founded on laboratory work, recitation and didactic teaching, is emphasized to the greatest possible degree. Fees: First year, $185; second and third, $180 each, and $195 for the fourth year. The Dean is Dr. Egbert Le Fevre. Total registration for 1905-6 was 481; graduates, 53. The next session opens Oct. 3, 1906, and closes June 6, 1907.

New York Homeopathic Medical College and Hospital.—This school, organized in 1858, has a faculty of 35 professors and 44 lecturers, instructors, etc., 79 in all. Flower Hospital, adjoining the college and having a completely equipped out-patient department; Metropolitan Hospital, New York Ophthalmic Hospital and the Laura Franklin Free Hospital for Children also furnish clinical facilities. The course covers four years of seven months each. Total fees for the first year, $130; second, $130; third, $125, and $155 for the fourth year. The Dean is Dr. W. H. King, 64 West Fifty-first St. Total students registered for 1905-6 was 110; graduates, 30. The next session begins Oct. 2, 1906, and ends May 16, 1907.

New York Medical College and Hospital for Women.—Homeopathic. This school was organized in 1863 and has a faculty of 17 professors, 21 lecturers and assistants, total 38. The college hospital and dispensary, the Memorial Hospital for Women, Metropolitan, Ophthalmic and the Laura Franklin Free Hospital for Children afford clinical material. The course covers four years of twenty-six weeks each. Fees: First year, $145; second, $140; third, $135, and $155 for the fourth year. The Dean is Dr. Helen Cooley Palmer, 5 West Eighty-second St. Total registration for 1905-6 was 20; graduates, 6. The next session opens Oct. 1, 1906, and closes May 14, 1907.

Eclectic Medical College of the City of New York.—This was organized in 1865 and has a faculty of 16 professors and 17 lecturers, demonstrators, etc., 33 in all. A college dispensary, Beachonian Dispensary, Manhattan and Red Cross Hospitals and Muncie Sanatorium supply clinical facilities. The work covers four years of seven months each. The total fees: First year, $125; second, $125; third, $125, and $155 for the fourth year. The Dean is Dr. George W. Beskowitz. Total registration for 1905-6 was 105; graduates, 15. The next session opens Sept. 27, 1906, and closes May 1, 1907.

Albany.

Albany Medical College.—This school was organized in 1838, and in 1873 it assumed its present relations as Medical Department of Union University. The faculty is composed of 15 professors and 65 lecturers, instructors and assistants, a total of 80. Albany, St. Peter's, Child's and County hospitals, South End Dispensary, Eye and Ear Infirmary and the Albany Hospital for Incurables, also the free dispensaries connected with each, are open to students for clinical study. The curriculum embraces graded work for four years of seven and one-half months each. Teaching is carried on in the laboratories, clinics and lecture rooms. Examinations are held twice a year in all subjects. Fees: First year, $130; second year, $145; third year, $120, and fourth year, $130. The Dean is Dr. Samuel B. Ward. Total registration for 1905-6 was 165; graduates, 32. The next annual session opens Sept. 25, 1906, and closes May 7, 1907.

Buffalo.

University of Buffalo Medical Department.—This was organized in 1846 and has a faculty made up of 47 professors and 45 assistants, lecturers, etc., a total of 92. Buffalo General Hospital, Hospital of the Sisters of Charity, Erie County and German hospitals and the German Deaconess' Hospital supply ample clinical material for study. A college dispensary, recently organized, is also of value in practical work. The buildings and hospitals are well equipped for clinical and laboratory work. Bedside instruction is insisted on and the senior students are permitted to assist in operations and give anesthetics. This school is a member of the Association of American Medical Colleges. The course covers four years of eight months each. The tuition is $125 each year; this does not include laboratory fees. The Dean is Dr. Matthew D. Mann, 37 Allen St. Total registration for 1905-6 was 225; graduates, 44. The sixty-first session opens Sept. 24, 1906, and closes May 31, 1907.

Syracuse.

College of Medicine, Syracuse University.—This school was organized in 1872 as the Medical Department of Syracuse University. The faculty is composed of 14 professors and 40 lecturers, instructors, etc., in all 54. Clinical facilities are furnished by St. Joseph's Hospital, Hospital of the Good Shepherd, Syracuse Hospital for Women and Children, Onondaga County Orphan Asylum and the Syracuse Free Dispensary. The laboratories and amphitheaters are large and well equipped. The curriculum embraces a four years' graded course, eight months making a school year. The average total fees for each of the four years is $167.25. The Dean is Dr. Gaylord P. Clark, 619 West Genessee St. Total number of students registered for 1905-6 was 153; graduates, 23. The next session opens Oct. 2, 1906, and closes June 12, 1907.

NORTH CAROLINA.

North Carolina, population 1,893,810, has four medical schools which grant degrees and one which gives only the first two years of the medical course. The Medical Department of the University of North Carolina is located at Chapel Hill, population 1,100, and at Raleigh, population 13,934. The Leonard School of Medicine is at Raleigh. The North Carolina Medical College is located at Davidson, population 904, and at Charlotte, population 20,050. Wake Forest School of Medicine is at Wake Forest, population 823.

Chapel Hill and Raleigh.

University of North Carolina Medical Department.—This school was organized in 1891 and formerly gave only the work of the first two college years at Chapel Hill. In 1902 the course was extended to four years by the establishment of a department at Raleigh, in which the last two years are given. Degrees are now conferred and the faculty in the completed school of medicine numbers 39. It is a member of the Association of American Medical Colleges. The number of students enroled in 1905-6 was 94, graduates, 11. Total fees are $85 per year. Board, room, light and heat may be had for from $84 to $102 per college year. The President is Dr. F. P. Venable, Chapel Hill. The Dean of the Department at Raleigh is Dr. H. A. Royster. The next session will begin Sept. 10, 1906, and end June 7, 1907.

Raleigh.

Leonard School of Medicine.—Colored. This department of Shaw University was established in 1882 by the American Baptist Home Mission Society to train colored students of medicine. It has a faculty of 10. A free hospital and dispensary supply clinical material. A preliminary entrance examination is given to applicants not possessing a certificate or diploma of educational requirements. The course covers four years of seven months each. The total fees for each year are $75. The dormitory plan is adopted generally, and board and room cost $2 a week. The Dean is Dr. James McKee. Total enrolment for 1905-6 was 147; graduates, 33. Next session opens Oct. 1, 1906, and closes May 1, 1907.

Davidson and Charlotte.

North Carolina Medical College.—This school was organized in 1893 and has a faculty of 16 professors and 8 assistants, a total of 24. The Presbyterian Hospital in Charlotte supplies the clinical facilities. The course covers four years of eight months each, the last two years being given at Charlotte. Fees: First three years, $85 each, and $100 for the fourth year. The President is Dr. J. P. Monroe, of Davidson. Dr. I. W. Faison, Charlotte, is Dean of the Charlotte faculty. The total registration for 1905-6 was 92; graduates, 24. The next session begins Sept. 6, 1906, and closes April 15, 1907.

Wake Forest.

Wake Forest School of Medicine.—This school was organized in 1902. It only gives the first two years of the medical course. Each annual course extends over nine months. The school is a member of the Association of American Medical Colleges. It has a faculty of 10 and last year enroled 20 students. The fees are $85 a year. The Dean is Dr. Frederick K. Cooke. The next session opens Aug. 29, 1906, and closes June 1, 1907.

NORTH DAKOTA.

North Dakota, population 319,146, has one medical college, the College of Medicine of the State University of North Dakota, which is situated at University. Only the first two years of the medical course are given, which may be elected as the last two years of the A.B. degree.

University.

University of North Dakota College of Medicine.—This department was organized in 1905. The faculty is composed of 5 professors and 7 instructors, a total of 12. The course consists of two years' academic work and two years of medical college subjects, occupying nine months each year. The completion of this work in a satisfactory manner entitles the student to the A.B. degree from this institution, and a certificate of completion of the medical subjects embraced in the course. The total fees for each of the medical subject years are $50. The Dean is M. A. Brannon. The enrolment during 1905-6, the first session, was 7. The second session begins Sept. 25, 1906, and closes June 13, 1907.

OHIO.

Ohio, population 4,157,545, has ten medical colleges. Four of these, the Medical College of Ohio, Eclectic Medical Institute, Miami Medical College and Pulte Medical College are located in Cincinnati, a city of 332,934 inhabitants. The clinical advantages of Cincinnati are good; beside many smaller hospitals, the Cincinnati Hospital is open to the students for study. Board can be procured in Cincinnati for from $3 to $5 per week. The Laura Memorial Woman's Medical College has ceased to exist.

Cleveland, population 414,950, contains three medical schools: Western Reserve University Medical College, Cleveland College of Physicians and Surgeons and the Cleveland Homeopathic Medical College. The City Hospital, with 275 beds, is used in common by them for clinical study. Board and lodging can be had for from $2.50 to $5 a week.

Columbus, population 135,487, contains two; Starling Medical College and Ohio Medical University. Board and lodging cost from $2.50 to $5 per week.

Toledo, with 145,901 people, has one medical school, Toledo Medical College. It has good clinical advantages. Board and room can be had for from $3 to $5 a week.

Cincinnati.

Medical College of Ohio.—This is the Medical Department of the University of Cincinnati, organized in 1819, and has a faculty made up of 25 professors, 24 lecturers and assistants, a total of 49, there being also 34 clinicians to the dispensary. Good Samaritan Hospital, with 100 beds; Cincinnati Hospital, with 550 beds, furnish opportunities for bedside instruction, and a well-equipped college dispensary furnish clinical facilities. The buildings supply ample laboratory and lecture-room space and their equipment is good. The course of study is graded and covers four years of eight months each. This school is a member of the Association of American Medical Colleges. The lecture fees are $125 each year for each student entering after July 1, 1903; $100 each year for those who have matriculated prior to July 1, 1903. In addition there is a matriculation fee of $5, payable but once, and a graduation fee of $25. Total registration of students for 1905-6 was 137; graduates, 33. The Dean is Dr. F. Forchheimer. The next session begins Sept. 28, 1906, and ends June 1, 1907.

Miami Medical College.—This school was organized in 1852 and has a faculty of 22 professors and 29 lecturers and demonstrators, a total of 51. The clinical facilities are furnished by the Cincinnati Hospital and a college dispensary. This college is a member of the Association of American Medical Colleges. The curriculum embraces a four-year graded course of eight months each. The total fees are, for the first year, $130; for the second and third, $125, and $150 for the fourth year. The Dean is Dr. J. C. Oliver, 628 Elm St. The total registration for 1905-6 was 78; graduates, 24. The next session opens Oct. 1, 1906, and closes June 1, 1907.

Eclectic Medical Institute.—This school, organized in 1845, has a faculty of 17 professors and 12 lecturers and assistants, a total of 29. The Seton Hospital, Cincinnati Hospital and a college dispensary furnish clinical material. It is a member of the National Confederation of Eclectic Medical Colleges. The course covers four years of thirty-one weeks each. The fees are $75 for each year, with a graduation fee of $25. The Dean is Dr. Rolla L. Thomas, 792 East McMillan St. Total enrolment, 1905-6, was 116; graduates, 35. The next session begins Sept. 17, 1906, and closes April 17, 1907.

Pulte Medical College.—Homeopathic. This was organized in 1872 and has a teaching force of 20 professors and 14 assistants, 34 in all. Pulte Hospital, Cincinnati Hospital, Bethesda Hospital, Home of the Friendless and Foundlings and a college dispensary supply clinical material. The curriculum covers four years of seven months each. Fees: First year, $80; for the second and third, $75 each, and $100 for the fourth. The Dean is Dr. Charles E. Walton. Total enrolment for 1905-6 was 13; graduates, 3. The next session opens Oct. 3, 1906, and closes May 1, 1907.

Cleveland.

The Cleveland College of Physicians and Surgeons.—This school was organized in 1863 as Charity Hospital Medical College, became the Medical Department of Wooster University in 1869 and the Medical Department of the Ohio Wesleyan University in 1896, when it assumed its present title. The faculty is composed of 31 professors, 30 lecturers, assistants, instructors, etc., 61 in all. Cleveland General Hospital, Cleveland City Hospital and a college dispensary are used for regular clinical teaching. St. Alexis, St. John's, St. Clair and Mount Sinai hospitals are utilized for extramural clinics. This school is a member of the Association of American Medical Colleges. The school is co-educational. The total annual fees are $130. The curriculum covers four years of eight months each. The Dean is Dr. R. E. Skeel, 785 Prospect St. Total enrolment for 1905-6 was 88; graduates, 22. The next term opens Oct. 1, 1906, and closes May 22, 1907.

Western Reserve University Medical College.—The Medical Department was organized in 1843. Its teaching faculty includes 22 professors, 34 lecturers, demonstrators and assistants, a total of 56. Clinical facilities are offered students of this school by Lakeside Hospital, having 250 beds; St. Vincent's Hospital, having about 150 beds; City Hospital, with 250 beds; St. Alexis Hospital, with 250 beds, and the Home of Maternity, with the dispensary service at Lakeside and Charity hospitals, and a tuberculous dispensary at the college. The laboratory chairs are endowed, the teachers devoting their entire time to teaching and research work. A clinical laboratory has recently been added, where a systematic course of instruction is given. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight and one-half months each. Three years of college work are required for admission to first year of medical course. The total fees are $125 for each year. The Dean is Dr. B. L. Millikin, 1110 Euclid Ave. Total enrolment for 1905-6 was 65; graduates, 12. The next session begins Oct. 1, 1906, and closes June 13, 1907.

Cleveland Homeopathic Medical College.—This school was founded in 1897 by a consolidation of Cleveland University of Medicine and Cleveland Medical College, the former of which was incorporated in 1850, and is the second oldest homeopathic medical college in the United States. The faculty includes 35 professors and 18 adjuncts, lecturers, etc., 53 in all. The clinical facilities are obtained from the Cleveland Homeopathic Hospital, the Cleveland City Hospital, the Cleveland Maternity Hospital, and a college dispensary. The course embraces four years of thirty weeks each. Fees, $125 per year. The Dean is Dr. George H. Quay. Total number of students registered, 1905-6 was 50; graduates, 14. The next session opens Sept. 26, 1906, and closes May 15, 1907.

Columbus.

Ohio Medical University.—This school was organized in 1890, and has a faculty of 22 professors, 6 instructors, 5 assistants and 2 demonstrators, 35 in all. The Protestant Hospital, State Hospital, Ohio Penitentiary Hospital and a college dispensary provide material for clinical work. This school is a member of the Association of American Medical Colleges. The course is four years of 34 weeks each. Fees: First year, $105; second year, $100; third year, $100, and $110 for the fourth year. The Dean is Dr. George M. Waters. Total students for 1905-6 was 142; graduates, 42. The next session begins Sept. 11, 1906, and closes May 7, 1907.

Starling Medical College.—This school was organized in 1847 and has a faculty composed of 19 professors and 20 lecturers, associates, etc., a total of 39. St. Francis Hospital, which is under the control of this faculty; Hawkes' Hospital of Mt. Carmel, the Lawrence Hospital, St. Anthony Hospital and a college dispensary are available for clinical study. This college is a member of the Association of American Medical Colleges. The work covers four years of thirty weeks each. Fees: $100 per year; matriculation fee, $5; graduation fee, $10. The Dean is Dr. Charles S. Hamilton. Enrolment for 1905-6 was 86; graduates, 30. The sixtieth session opens Sept. 12, 1906, and closes May 9, 1907.

Toledo.

Toledo Medical College.—The school was organized in 1882, and in 1904 became the Medical Department of Toledo University. It has a faculty of 20 professors, 20 lecturers and assistants, in all 40. Toledo Hospital, St. Vincent's and Robinwood hospitals, Lucas County Infirmary Hospital, Toledo Hospital for the Insane, and a free dispensary supply clinical facilities. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight months each. The fees are $75 for each year, with a matriculation fee of $5, payable once. The Dean is Dr. Park L. Myers, 2730 Monroe St. Total enrolment for 1905-6 was 22; graduates, 9. The next session opens Sept. 22, 1906, and closes May 11, 1907.

OKLAHOMA.

Oklahoma, population 398,331, has two medical schools, the School of Medicine of the University of Oklahoma, which is located at Norman, a city of 2,225 inhabitants, and the College of Medicine of Epworth University, located at Oklahoma City, which has a population of 12,800.

Norman.

School of Medicine, University of Oklahoma.—This school was organized in 1903 and gives only the first two years of the medical course, each session extending over a period of nine months. Two courses are offered, one covering two years, at the completion of which a certificate is given; the other a combined course of four years, leading to the degree of B.S. Students are encouraged to take the latter course. The college has a faculty of 10. The school is a member of the Association of American Medical Colleges. Total registration for 1905-6 was 16. The Dean is Dr. R. P. Stoops; the Corresponding Secretary E. M. Williams. The next session begins Sept. 11, 1906, and ends June 13, 1907.

Oklahoma City.

College of Medicine Epworth University.—Organized in 1904, giving only the first year of the medical course. The full four years' course has been given since Oct. 1, 1905. The faculty consists of 15 professors and 12 assistants, instructors, etc., a total of 27. the Oklahoma City, and St. Anthony's hospitals, Amie Rescue Home and a college dispensary furnish material for clinical instruction. The laboratories are well supplied and the lecture rooms are large, well lighted and well ventilated. The entrance requirement is a high school diploma or its equivalent. The course of study embraces graded work for four years of seven months each. The total fees are about $70 each year. The Dean is Dr. A. K. West; Secretary, Dr. H. C. Todd. The registration for 1905-6 was 16; no graduates. The next session begins Oct. 7, 1906, and ends May 7, 1907.

OREGON.

Oregon, population 413,536, has two medical colleges: Medical Department Willamette University, located in Salem, a city of 4,258 people, and University of Oregon Medical Department, in Portland, a city of 98,655 population. Board and lodging may be obtained in Salem for from $3 to $5 per week and in Portland for from $4 to $6.

Salem.

Medical Department Willamette University.—The school was organized in 1864. The faculty consists of 16 professors and 3 assistants, a total of 19. Clinical facilities for study are supplied by Salem Hospital, and a college dispensary. This school is a member of the Association of American Medical Colleges. The course embraces four years' work of seven months each. Fees: First and second years, $110 each; third, $75, and $50 for the fourth year. The Dean is Dr. W. H. Byrd. Total enrolment for 1905-6 was 50; graduates, 15. The next session begins Oct. 1, 1906, and ends May 10, 1907.

Portland.

University of Oregon Medical Department.—This department of the State University was organized in 1887, and has a faculty of 14 professors and 22 assistants, lecturers, etc., a total of 36. Good Samaritan and St. Vincent's hospitals, containing 200 and 350 beds, respectively, and Multomah County Hospital furnish good material for clinical study. Out-patient clinics are held at Pilgrim Chapel. The requirements for admission are those of the Association of American Medical Colleges, but the members of the faculty do not hold examinations for entrance. The college building is modern and well equipped, presenting ample teaching facilities. The course is four years of seven and one-half months each. Fees: First year, $142.50; second, $137.50; third, $107.50, and for the fourth, $57.50. The Dean is Dr. Simeon E. Joseph. The total number of students for 1905-6 was 82; graduates, 16. The next session opens Sept. 17, 1906, and closes May 1, 1907.

PENNSYLVANIA.

Pennsylvania, population 6,302,115, has seven medical colleges. Of these Philadelphia, having a population of 1,367,716, contains six, as follows: University of Pennsylvania Department of Medicine, Jefferson Medical College, Hahnemann Medical College, Woman's Medical College of Pennsylvania, Medico-Chirurgical College of Philadelphia and Temple College Department of Medicine. The clinical facilities of Philadelphia present abundant and varied material for study. Beside the individual hospitals connected with each of the schools the charity hospitals are open to all the students in common. Board and lodging cost from $4 a week upward.

The other school, Western Pennsylvania Medical College, is situated in Pittsburg, a city of 345,043 people. The cost of board and lodging is from $4 to $6 a week.

Philadelphia.

University of Pennsylvania Department of Medicine.—This is the first medical college established in this country, having been organized in 1765 as the Medical Department of the College of Philadelphia; the first degree was granted in 1768. When from the College of Philadelphia the University of Pennsylvania was organized in 1791, it became the Medical Department of the University, its present relation. The faculty is made up of 27 professors, 2 associate professors, 4 adjunct professors, 6 assistant professors, 106 demonstrators, lecturers, associates, instructors, etc., a total of 145. Abundant and varied clinical material is furnished by the University Hospital, capacity 300 beds, which treats over 14,000 cases annually; University Maternity Pavilion, with 50 beds; Philadelphia Hospital, containing 1,000 beds; Pennsylvania Hospital, Children's Hospital and the Southeastern Hospital and Dispensary. Special attention is paid to bedside instruction and to thoroughly practical work. Applicants for admission must furnish evidence of the education required to enter the academic department of the university. The buildings known as Medical Hall, Medical Laboratory Building, the laboratories of Pathology, Physiology and Pharmacology, the Laboratory of Hygiene, the Wistar Institute of Anatomy, and the Wm. Pepper Clinical Laboratory supply excellent laboratory and lecture room facilities and are well equipped. The course embraces study for four years of nine months each. The total fees for each year are $200, with a matriculation fee of $5 for the first year. The Dean is Dr. Charles H. Frazier. Total enrolment for 1905-6 was 577; graduates, 103. The next session opens Sept. 28, 1906, and closes June 19, 1907.

Jefferson Medical College of Philadelphia.—This school was organized in 1825, and has a faculty of 31 professors and 82 lecturers, demonstrators, etc., a total of 113. Jefferson Hospital, together with its maternity Department, are used exclusively by students of the school for clinical study. Bedside instruction is given daily to small sections of the senior class. In addition, the following hospitals are open for study of clinical cases: Pennsylvania, Philadelphia, St. Joseph's, German, Municipal and Wills Eye hospitals. The course of study covers graded work of four years of eight months each. The laboratories are large and well equipped, a new five-story laboratory building having recently been added; the lecture rooms and amphitheaters are also ample. A new fireproof hospital is now building, to cost $1,000,000, to be finished in 1906. The tuition is $180 a year, with a matriculation fee of $5, paid but once. The Dean is Dr. James W. Holland. The total number of students for 1905-6 was 617; graduates, 200. The next session opens Sept. 24, 1906, and closes June 4, 1907.

Medico-Chirurgical College of Philadelphia.—This school was organized in 1881, and has a faculty made up of 25 professors and 58 assistants, lecturers, etc., 83 in all. Opportunities for clinical study are offered exclusively to students of this school by the Medico-Chirurgical Hospital, with 125 beds, and its children's and maternity hospital, having 30 beds. In common with other schools, the following are used: Philadelphia, Pennsylvania, German, Samaritan, St. Joseph's, St. Agnes', St. Mary's, Methodist, Jewish and the Philadelphia Lying-in hospitals. With new laboratories, lecture rooms, a modern hospital and fine clinical amphitheater, this college is amply provided and the equipment is good. The work embraces four years of eight months each. Fees: $150 per annum; matriculation, $5, payable once. The Dean is Dr. Seneca Egbert. Total enrolment, 1905-6 was 467; graduates, 84. The next session opens Sept. 24, 1906, and will close June 1, 1907.

Woman's Medical College of Philadelphia.—This school was organized in 1850, and has a faculty of 10 professors and 37 assistants, lecturers, etc., in all 47. Clinical facilities are offered by the Hospital of the Woman's Medical College of Pennsylvania, Woman's Hospital, West Philadelphia Hospital for Women, German, Jewish, Children's and Philadelphia hospitals, Presbyterian Hospital, Wills Hospital for Diseases of the Eye, the Howard Hospital and the Philadelphia Lying-in Charity. The lecture room and laboratory equipment is good. The curriculum covers four years of eight months each. Fees: $140 each year. The Dean is Dr. Clara Marshall. Total enrolment for 1905-6 was 136; graduates, 25. The next session begins Sept. 26, 1906, and will end May 22, 1907.

Hahnemann Medical College and Hospital.—Homeopathic. This was organized in 1848 and has a faculty of 30 professors and 44 lecturers, instructors, etc., in all 74. Hahnemann College Hospital furnishes material for clinical work. The requirements for admission are those established by the Medical Council of Pennsylvania. The work covers four years of eight months each. Fees: For each year, $150; matriculation, $5. Total number of students for 1905-6 was 186; graduates, 52. The Dean is Dr. Herbert L. Northrop. The next session begins Sept. 25, 1906, and will end May 24, 1907.

Medical Department of the Temple College.—This department was organized in 1901, and has a faculty of 18 professors and 32 assistants, etc., a total of 50. Instruction is given in the evening, and the course extends over five years of nine months each. The fees are $125 per year. The Dean is Dr. I. Newton Snively. The enrolment for 1905-6 was 101; graduates, 14. School opens Sept. 15, 1906, and closes June 11, 1907.

Pittsburg.

Western Pennsylvania Medical College.—This is the Medical Department of the Western University of Pennsylvania, and was organized in 1886. The faculty is composed of 47 professors and 57 associates, assistants, etc., 104 in all. Clinical material for study is furnished by a college dispensary, and the Emma Kaufman Clinic, Reineman Maternity Hospital, Mercy, South Side, Passavant and St. John's hospitals. This school is a member of the Association of American Medical Colleges. The course of study embraces graded work for four years of nine months each. Special attention is given to practical bedside work. The total fees are $150 for each year. The Dean is Dr. J. C. Lange. Total enrolment for 1905-6 was 307; graduates, 46. The next session begins Oct. 1, 1906, and will close June 12, 1907.

PHILIPPINE ISLANDS.

Manila.

University of Saint Thomas Medical Department.—The University was founded by a papal decree in 1587, and the medical school was added in 1871. The faculty consists of 19 professors. The course extends over a period of six years of nine months each. The first year is a preparatory one, devoted to the teaching of physics, chemistry and biology. The degree of licenciado is conferred at the conclusion of the fifth year, and the degree of doctorado at the end of the sixth year, during which only special work is done. This last year is optional, the degree of licenciado entitling the holder to all the rights and privileges of the medical practitioner. The degree is equivalent to the English M.B. The Rector of the university is Dr. Fr. Raymundo Vetasquez; the Secretary of the medical department is Lic. Blas C. Alcuaz. Total registration for 1904-5 was 310; given degree of *licenciado*, 26: given M.D., 11. The course began July 2, 1905, and ended March 6, 1906.

SOUTH CAROLINA.

South Carolina, population 1,340,316, has one medical college, situated in Charleston, a city of 56,062 people. Board and room can be obtained for from $12 to $16 a month.

Charleston.

The Medical College of the State of South Carolina.—This school was founded in 1823. The faculty is made up of 10 professors and 10 assistants, etc., 20 in all. The clinical facilities are those offered by the New Roper Hospital, capacity 150 beds and having indoor and outdoor departments, where surgical, obstetrical and medical instruction is given. Applicants for matriculation must show diplomas of graduation from some literary or scientific institution of learning or certificates from some legally constituted high school or evidences of education satisfactory to the faculty. The course covers four years of six months each. The total fees for each of the first two years are $100, and $75 each for the last two. The Dean is Dr. Edward F. Parker. Total enrolment for 1905-6 was 97; graduates, 8. The next session opens Oct. 2, 1906, and closes April 15, 1907.

TENNESSEE.

Tennessee, population 2,020,616, has eleven medical colleges. Of these the Medical Department of the University of Nashville, Vanderbilt University Medical Department, University of Tennessee Medical Department and Meharry Medical College are situated in Nashville, a city with a population of 80,865. The City Hospital, containing 100 beds, is used by all the schools in common for clinical study. Board and lodging cost from $3 to $4 a week.

Knoxville, population 34,344, contains two colleges, Tennessee Medical College and Knoxville Medical College. The cost of room and board in that city is from $2.50 to $4 a week.

Chattanooga Medical College and Chattanooga National Medical College are situated in Chattanooga, a city of 30,469 people. Board and lodging cost there from $2 a week upward.

Memphis Hospital Medical College and the College of Physicians and Surgeons are located in Memphis, population 113,669. Good board can be obtained for from $3 to $4 a week.

The University of West Tennessee is in Jackson, whose population is 15,852.

The other school, the Sewanee Medical College, is located at Sewanee, a mountain town of 600 people.

Nashville.

University of Nashville Medical Department.—This school, established in 1850, has a faculty of 11 professors and 12 lecturers, assistants, etc., in all 23. This school is a member of the Southern Medical College Association. The course of study covers four years of twenty-six weeks each. The tuition for each of the four years is $75. The Dean is Dr. William G. Ewing. Total enrolment for 1905-6 was 298; graduates, 42. The next session begins Oct. 1, 1906, and ends March 29, 1907.

Vanderbilt University Medical Department.—This school was founded in 1874, and in 1895, when the present medical building was completed, the course was extended, the standard raised. The present faculty of 35 consists of 20 professors and 15 lecturers, etc. The school is a member of the Southern Medical College Association. The course covers four years of seven months each. The minimum entrance requirement is a high school diploma or its equivalent. The total fees for the first three years are $105 each and $130 for the fourth year. The Dean is Dr. William L. Dudley. Total enrolment for 1905-6 was 197; graduates, 36. The next session begins on or about Oct. 1, 1906, and ends May 1, 1907.

University of Tennessee Medical Department.—This was organized in 1876 as the Nashville Medical College; its present relations were assumed in 1879. The faculty is composed of 16 professors and 10 lecturers, assistants, etc., 26 in all. The school is a member of the Southern Medical College Association. The course of study includes work for four years of seven months each. The total fees for each of the first three years are $75 and $100 for the fourth year. The Dean is Dr. Paul F. Eve, 614 Broad St. Total enrolment for 1905 6 was 182 students; graduates, 25. The next session begins Oct. 1, 1906, and ends May 1, 1907.

Meharry Medical College.—Colored. This school was organized in 1876 as the Medical Department of Central Tennessee College, now Walden University, "for the purpose of furnishing to the colored people of the South an opportunity of obtaining a medical education." The faculty is made up of 12 professors and 13 instructors, demonstrators, etc., 25 in all. The work embraces a four-year graded course, seven months to the year. The total fees for the first three years are $50 each, and $60 for the fourth year. The Dean is Dr. G. W. Hubbard. Total registration for 1905-6 was 321; graduates, 68. The next session begins Sept. 5, 1906, and ends April 5, 1907.

Knoxville.

Tennessee Medical College.—This school was organized in 1889, and has a faculty of 14 professors and 12 assistants, 26 in all. This school is coeducational. The Tennessee Medical College is now the medical department of the Lincoln Memorial University. A new college building with large and well-filled laboratories has been completed. The Lincoln Memorial Hospital, owned and controlled by the faculty, adjoins the college building and furnishes material for clinical study. This school is a member of the Southern Medical College Association. The curriculum includes graded work for four years of seven months each. Fees: First and second years, $50; third and fourth years, $60; matriculation fee, $5; graduation fee, $25. The Registrar is Dr. E. R. Zemp. Total number of students for 1905-6 was 80; graduates, 19. Next session begins Nov. 1, 1906. and closes about June 1, 1907.

Knoxville Medical College.—Colored. This school was established in 1900, following the discontinuance of the Medical Department of Knoxville College. organized in 1895. The teaching force comprises 12. The course covers four years of seven months each. Fees, $40 per year. The Secretary is Dr. H. M. Green. Total number of students for 1905 6 was 45; graduates, 4. The next session opens Nov. 10, 1906, and closes June 1, 1907.

Chattanooga.

Chattanooga Medical College.—This is the Medical Department of Grant University and was organized in 1889. The faculty consists of 10 professors and 16 instructors, demonstrators, etc., total 26. Adequate clinical facilities are afforded by the wards of Baroness Erlanger Hospital, a county asylum, an outdoor clinic maintained in the college building, and all material furnished by the city physician's office which the faculty desires to utilize. The scholastic requirements are those of the Southern Medical College Association, of which this school was a charter member and to which it belongs. These requirements involve a strictly graded course covering four years of seven months each. The total fees approximate $55 each session. The trustees materially added to the general facilities of the institution by the erection of another fine four-story building of brick and stone for the medical department three years ago, wherein much modern and elaborate equipment has been installed. The Dean is Dr. J. R. Rathmell. The total enrolment for the session of 1905-6 was 267; graduates, 33. The next session opens about Oct. 1, 1906, and ends April 30, 1907.

Memphis.

Memphis Hospital Medical College.—This school, organized in 1878, has a faculty of 10 professors and 18 assistants, beside quiz masters. Excellent clinical facilities are furnished by the City Hospital, Presbyterian Hospital, St. Joseph's Hospital and the East End Dispensary, the latter being located in the college building. The course includes graded work for four years of seven months each. The total fees for the first three years are $75; for the fourth, $100. The Dean is Dr. W. B. Rogers. Total registration for 1905-6 was 492; graduates, 82. The twenty-seventh annual session will begin Oct. 1, 1906, and close April 30, 1907.

College of Physicians and Surgeons.—This college was organized in 1906 and has a faculty of 20. The new building will be ready for the beginning of the first course of lectures, which will start October 1. The Memphis City Hospital is immediately opposite the college building. Access will also be had to St. Joseph's, Presbyterian and Lucy Brinkley hospitals. Laboratories will be well equipped. The course will cover four years of seven months each. The Dean is Dr. Heber Jones, Tennessee Trust Building.

Jackson.

Medical Department of the University of West Tennessed.—Colored. This school, organized in 1900, has a faculty of 10. The course is four years of seven months each. The fees are $40 per year; graduation, $10 extra. Registration for 1905-6 was 40; graduates, 4. The next session opens Sept. 24, 1906, and closes April 24, 1907.

Sewanee.

Medical Department of the University of the South.—This school was organized in 1892 and has a faculty of 21 members. It is a member of the Southern Medical College Association. The required curriculum is four courses of seven months each, with an interval of eleven months between matriculations. The requirements for entrance on the study are a recommendation from two well-known physicians and a certificate of a high school training. The Dean is Dr. J. S. Cain. Total enrolment for 1905-6 was 119; graduates, 28. The fourteenth course opened April 2, 1906, and closes Oct. 30, 1906.

TEXAS.

Texas, population 3,048,710, has seven medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 37,789 inhabitants. Good board and room can be procured for from $15 to $20 a month.

The Medical Department of Fort Worth University is at Fort Worth, population 27,192. The cost of board and room in that city is from $12 to $15 a month.

The Baylor University College of Medicine, the Medical Department of Southwestern University, the College of Physicians and Surgeons and the Physio-Medical College of Texas are situated in Dallas, population 44,159.

The Gate City Medical College is situated in Texarkana, having a population of 5,256.

Dallas.

Baylor University College of Medicine.—This is a new name for the University of Dallas Medical Department, which was organized in 1901. In June, 1903, it became the Medical Department of Baylor University at Waco. In 1905 it merged with the Dallas Medical College. The faculty numbers 20 professors and 16 assistants, total 36. Parland Hospital, with 90 beds; St. Paul's Sanitarium, Baptist Memorial Hospital and a college dispensary and hospital are utilized for clinical study. The course covers four years of seven months each. The school is a member of the Association of Southern Medical Colleges. The fees are $75 for each of the four years, with a matriculation fee of $5, paid once, and a graduation fee of $25. The Dean is Dr. E. H. Cary. Total registration for 1905-6 was 70; graduates, 8. The next session opens Oct. 1, 1906, and closes May 1, 1907.

Southwestern University Medical College.—This is the Medical Department of Southwestern University and was organized in June, 1903. It has a faculty of 17 professors and 14 instructors, total 31. The course of instruction is graded and covers four years in medicine and two in pharmacy. Requirements for admission are equivalent to those prescribed by the Association of American Medical Colleges. The fees are: Matriculation, $5, paid once; annual tuition, $75; graduation, $25. The hospitals represented by the faculty and open for clinical teaching are St. Paul's Sanitarium, City Hospital, Texas Baptist Memorial Hospital, Children's Home. Mission Home, Woman's Home, St. Joseph Orphanage, St. Matthew's Home for Children, Dr. H. K. Leake's Private Infirmary and Outdoor Clinic of the Settlement Home. The Dean is Dr. John O. McReynolds. Total registration, 1905-6, was 85; graduates, 7. The fourth session opens Oct. 1, 1906, and closes May 3, 1907.

College of Physicians and Surgeons.—This school was founded in 1904 as the Bell Medical College, and in 1905 the name was changed to the above. It has a total teaching staff of 15. The course of instruction extends over four years of six months each. The requirements for admission are the same as those prescribed by the Association of Southern Medical Colleges. Clinical instruction is given in the City Hospital, St. Paul Sanitarium and the college dispensary. The fees for the first three years are $80, and $105 for the fourth year. The Dean is Dr. Arthur C. Bell. Total registration for 1905 6 was 95; graduates, 18. The next session begins Oct. 2, 1906, and closes April 3, 1907.

Physio-Medical College of Texas.—This college was organized in 1902. It has a faculty of 22 professors and 4 assistants, total 26. The course is four years of thirty weeks each. The fees are, first year, $70; fourth year, $85; other years, $65. Enrolment, 1905-6, was 47; graduates, 11. The secretary is Dr. R. L. Spann. The next session opens Oct. 15, 1906, and closes May 15, 1907.

Galveston.

University of Texas Medical Department.—This department of the State University was organized in 1891 and has a faculty of 23. The John Sealy Hospital, also having an outdoor department, and St. Mary's Infimary supply good material for clinical study. Requirements for admission: (*a*) Admission Without Examination.—Graduates of approved schools and colleges, graduates of affiliated high schools, holders of first-grade state teachers' certificates and students of approved colleges and universities are admitted without entrance examination. (*b*) Admission on Examination.—Examinations on the following prescribed subjects are required to begin the study of medicine: English, 3½ units; history, 1½ units; algebra, 1½ units, and 1½ units in either geometry, Latin or physics. (A unit is a high-school course pursued for one session.) For full admission credit must be secured in five additional units from elective subjects in languages and sciences if Latin be included, or in six units if Latin be not included. Students who do not secure credit for all the electives at the time of entrance may do so during the summer vacations, but they must do so before they can become candidates for the degree. The curriculum embraces graded work for four years of eight months each. All laboratories are completely equipped. Fees: First year, $50; second and third, each $20, and $5 for the fourth. The Dean is Dr. William S. Carter. Total registration for 1905-6 was 189; graduates, 31. The next session begins Oct. 1, 1906, and ends May 31, 1907.

Fort Worth.

Medical Department of Fort Worth University.—This school was organized in 1894 and has a faculty of 15 professors and 22 lecturers, assistants, etc., in all 37. Clinical facilities are supplied by St. Joseph's Hospital, with 200 beds; the Benevolent Home, containing 75 beds; the Gelia Collins' Rescue Home, having 50 beds, and a college dispensary. The school is a member of the Southern Medical College Association. The course covers four years of seven months each. The total fees for each of the first three years are $75 and $100 for the fourth year. The Dean is Dr. Frank Gray. The total enrolment for 1905-6 was 192; graduates, 23. The next session opens Oct. 3, 1906, and closes May 3, 1907.

Texarkana.

Gate City Medical College.—The length of each course is seven months. The faculty numbers 20 professors and assistants. Registration, 1905-6, was 156; graduates, 40. The Dean is Dr. J. W. Decker. The next session begins Oct. 1, 1906, and ends May 4, 1907.

UTAH.

Utah, population 276,749, has one medical college, situated at Salt Lake City, which has 57,138 people. This college is the Medical Department of the University of Utah, which gives only the first two years of the medical course.

Salt Lake City.

University of Utah Department of Medicine.—This department was organized in 1906 and offers the first two years of the medical course, each year extending over thirty-six weeks. Two courses are offered, a two-year course of the standard medical course leading to a special certificate and a four-year course consisting of two years in the College of Arts, the two years in medicine being counted as the junior and senior years, which gives the A.B. degree and a special certificate. The medical faculty consists of 7 professors and 16 lecturers and assistants. a total of 23. Fees: V. Chamberlin, Ph.D. The enrolment for 1905-6, the first session, was 30. The second session begins Sept. 17, 1906, and ends June 6, 1907.

VERMONT.

Vermont, population 343,641, has one medical school, located at Burlington, a town of 19,885 people. Board and room cost from $3.50 to $5 a week.

Burlington.

University of Vermont College of Medicine.—This school was organized in 1822, but suspended from 1836 until 1854, when it was reorganized. The faculty consists of 21 professors and 21 assistants, instructors, etc., in all 42. The Mary Fletcher Hospital and a free dispensary furnish material for clinical instruction. Applicants for admission must be graduates of a four-year high school course or take an examination to show equivalent educational qualifications. The laboratory and lecture-room space and equipment are good. A new and commodious college building has just been completed and is now in use. The course of study embraces graded work for four years of seven months each. The total fees for each of the first three years are $115 and $140 for the fourth year. The Dean is Dr. H. C. Tinkham; Secretary, H. L. White, A.M. Total registration of students for 1905-6 was 169; graduates, 47. The fifty-fourth session begins Dec. 1, 1906, and ends June 28, 1907.

VIRGINIA.

Virginia, population 1,854,184, has three medical colleges, situated in Charlottesville, population 6,449, and Richmond, population 86,148. The clinical facilities in Richmond are good. Board and room can be obtained for $18 a month and upward in Charlottesville, and from $12 to $20 a month in Richmond.

Charlottesville.

University of Virginia Department of Medicine.—This school was organized in 1827 and has a faculty of 24. A free dispensary and the new four-story hospital furnish clinical facilities. The requirements for admission are those of the Association of American Medical Colleges. The course is four years of nine months each. Fees: First year, $110; second, $100; third, $80, and $60 for the fourth year. The Dean is Dr. R. H. Whitehead. Total enrolment for 1905-6 was 122; graduates, 21. The eighty-second session opens Sept. 13, 1906, and closes June 11, 1907.

Richmond.

Medical College of Virginia.—This school was organized in 1838 as the Medical Department of Hampden Sidney College, Virginia. In 1854 it was granted a charter by the legislature of Virginia as an independent institution under its present name. In 1860 the college and its appurtenances were deeded to the State of Virginia in consideration of an appropriation on the part of the state of a sufficient sum to build a hospital, since which time it has continued as a state institution. During the war between the states it was the only medical college in the Confederacy which did not close its doors. It held two sessions a year during this period, and a large proportion of the surgeons of the Confederate Army were graduates of this school. Clinical material was formerly furnished by the Old Dominion Hospital, but more recently by the Memorial Hospital, opened in July, 1903, and the City Free Dispensary, both of which are under the exclusive control of the college. The State Penitentiary Hospital and other public charities and asylums of the city afford ample opportunity for additional clinical work. This school is a member of the Southern Medical College Association. The buildings are large and numerous and contain well-equipped laboratories and amphitheaters. The course embraces four years of nearly eight months each. The fees are $100 for each year, with an additional graduation fee of $30. The Dean is Dr. Christopher Tompkins. Total registration for 1905-6 was 242; graduates, 45. The next session begins Sept. 25, 1906, and will end May 14, 1907.

University College of Medicine.—This school was organized in 1893 and has a faculty of 19 professors, 41 lecturers, assistants, etc., a total of 60. Good clinical facilities are furnished by Virginia Hospital, with a maternity department and annex, which was built especially for the purpose of affording bedside instruction and is owned and operated by the college; Richmond Eye, Ear and Throat Infirmary, containing 34 beds; the City Hospital, City Jail, State Penitentiary and a college dispensary. Matriculation is in accord with the rules of the Association of American Medical Colleges and of the Southern Medical College Association, to both of which this college belongs. The laboratory and lecture-room space and equipment are ample, and some of the instructors devote their entire time to the laboratories. The school lays especial importance on the careful instruction and guidance of each student. The curriculum covers four years of thirty-four weeks each. The total fees are $100 for each year. The President is Dr. Stuart McGuire; the Dean is Dr. Landon B. Edwards. Total enrolment for 1905-6 was 205; graduates, 20. The next session begins Sept. 25, 1906, and ends May 23, 1907.

WEST VIRGINIA.

West Virginia, population 958,800, has one medical college, College of Medicine of the West Virginia University, located at Morgantown, a city of 1,900 inhabitants.

Morgantown.

West Virginia University College of Medicine.—This school was organized in 1902 and gives only the first two years of the medical course. Each college term extends over nine months. The degree of M.D. is granted students after they finish the third and fourth years in Baltimore at the College of Physicians and Surgeons. The faculty consists of 5 professors and 4 assistants, 9 in all. The school is a member of the Association of American Medical Colleges. Tuition free to students residing in the state; for others, $37.50 per year. Dr. J. N. Simpson is the Dean and A. J. Collett the Secretary. Total registration in 1905-6 was 35. Next session begins Sept. 14, 1906, and closes June 14, 1907.

WISCONSIN.

Wisconsin, population 2,069,042, has two medical colleges, the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons. They are both situated in Milwaukee, a city of 312,736 people. Clinical facilities are furnished them in common by the County Hospital, with 300 beds, and the Milwaukee Hospital for the Insane. Board and lodging can be had for from $3 to $5 a week.

Milwaukee.

Milwaukee Medical College.—This school was organized in 1893 and has a faculty of 36 professors and 27 lecturers, instructors, etc., a total of 63. Good clinical material is furnished by Trinity and the County Hospitals, Milwaukee Hospital for the Insane and a college dispensary. This school is a member of the Association of American Medical Colleges. Ample laboratory and amphitheater facilities are afforded. The course covers four years of eight months each. The total fees are $125 each for the first three years and $135 for the fourth year. The President is Dr. William H. Earles. Total number of students for 1905-6 was 139; graduates, 15. The thirteenth session begins Sept. 18, 1906, and will close about May 14, 1907.

Wisconsin College of Physicians and Surgeons.—This college was organized in 1893 and has a faculty composed of 28 professors and 29 associates, assistants, etc., a total of 57. St. Joseph's Hospital, containing 150 beds; the college dispensary, the Milwaukee County Hospital and the Hospital for the Insane supply facilities for clinical study. The school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are well equipped. The curriculum includes four years of eight months each. Fees: Matriculation, paid once, $5; general ticket, $100 for the use of the microscope a fee of $2 is charged for each course

The Secretary is Dr. W. H Washburn Total enrolment for 1905 6 was 86; graduates 15 The next session begins Sept. 18, 1906, and ends May 16, 1907.

STANDARDS OF MEDICAL EDUCATION ADOPTED BY THE AMERICAN MEDICAL ASSOCIATION, JULY, 1905.

THE IDEAL STANDARD.

The ideal standard to be aimed at from the present viewpoint should consist of: (a) Preliminary education sufficient to enable the candidate to enter our recognized universities. the passing upon such qualifications by the state authorities (b) A five-year medical course, the first year of which should be devoted to physics, chemistry and biology, and such arrangements should be made that this year could be taken either in a school of liberal arts or in the medical school. Of the four years in pure medical work, the first two should be spent in laboratories of anatomy, physiology, pathology, pharmacology, etc, and the last two in close contact with patients in dispensaries and hospitals in the study of medicine, surgery, obstetrics and the specialties (c) A sixth year as an interne in a hospital or dispensary should then complete the medical course

Under such a scheme the majority of men would begin the study of medicine between 18 and 19 years of age, and would graduate from the hospital interneship at from 24 to 25. A college education is recognized as a desirable preparation for a limited number of men, but it is thought that it is not and never will be desirable to make such college education a requirement to the study of medicine, as it would make the age of graduation from 27 to 28 years. which is regarded as too old a period at which the young medical man should begin his life's work. It is obvious that this very desirable scheme of requirements can not be at once demanded or recommended.

STANDARD NOW RECOMMENDED.

The standard of requirements now recommended prerequisite to the practice of medicine consists of five cardinal points, as follows:

1. Preliminary requirements to be a high school education or its equivalent, such as would admit the student to one of our recognized universities
2. Preliminary requirements to be passed on by a state official, such as the superintendent of public instruction, and not by an official of the medical college.
3. A medical training in a medical college, having four years of not less than thirty weeks each year, of thirty hours per week of actual work.
4. Graduation from an approved medical college required to entitle the candidate to an examination before a state examining board.
5 The passing of a satisfactory examination before a state examining board.

HISTORY.

1. The above standards are the result of three conferences held by the Council on Medical Education of the American Medical Association at Philadelphia, December, 1904; at Chicago, April, 1905, and at Portland, July, 1905.

2. The Chicago meeting was a conference with representatives of (a) state examining and licensing boards, (b) government medical services, (c) associations of medical colleges and of (d) colleges of liberal arts.

3. Standards were reported to the American Medical Association. referred to a special reference committee and later adopted by the Association at the fifty sixth annual session, held at Portland, Ore, July 10 to 14, 1905.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

The requirements for admission and graduation to be maintained by colleges holding membership in this Association and the minimum course of study prescribed are as follows:

ARTICLE III

SECTION 1—Every college holding membership in this Association shall demand of each student under the condition hereinafter stated as a minimum requirement for admission to the medical course:

(a) A bachelor's degree from an approved college or university

(b) A diploma from an accredited high school, normal school or academy requiring for admission evidence of the completion of an eight year course in primary and intermediate grades, and for graduation not less than four years of study embracing not less than two years (4 points) of foreign language, of which one must be Latin, two years (4 points) of mathematics, two years (4 points) of English, one year (2 points) of history, two years (4 points) of laboratory science and six years (12 points) of further credit in language, literature, history or science.

(c) An examination in the following branches:

A. Required (18 points): Mathematics (4 points), English (4 points), History (2 points), Language (2 must be Latin); 4 points, Science (taken from physics, chemistry, botany, zoology), 4 points

B Optional (to 12 points): English, 2 points; History, 6 points, Language, 6 points; Manual Training, 2 points; Mechanical Drawing, 1 point; Natural Science (botany, biology, zoölogy), 2 points; Physical Science (chemistry, physics), 2 points; Trigonometry, 1 point, Astronomy (1), Civics (1), Geology (1), physical Geography (1), Physiology and Hygiene (1), Political Economy (1).

(One point in any subject in a high school or academic course demands not less than five periods per week of forty five minutes each for eighteen weeks)

(d) Certificates from reputable instructors recognized by any state board of medical examiners duly authorized by law or by the superintendents of public instruction in states not having a board of examiners, may be accepted in lieu of any part of this examination.

SEC 2—This examination must be conducted by or under the authority of the board of examiners or of the superintendent of public instruction of the city or state in which the college is located In no case shall it be conducted by any person connected with the faculty, medical or otherwise, of the institution to which the student is seeking admission.

SEC. 3—A student may be allowed to enter on his medical work conditioned in not more than six points, and these conditions must be removed by satisfactory examination before he is allowed to enter on the second year of his medical course.

SEC 4—Colleges in membership in this Association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of their course, but no member of this Association shall admit a student to advanced standing without first communicating with the college from which such student desires to withdraw, and receiving from the dean of such college a direct written communication certifying to the applicant's professional and moral qualifications and to the exact work he has done in said college.

SEC 5—Candidates for the degree of doctor of medicine shall have attended four courses of study in four calendar years, each annual course to have been of not less than thirty teaching weeks' duration, and at least ten months shall intervene between the beginning of any course and the beginning of the preceding course

SEC 6—Credit may be given to the holder of a bachelor's degree from an approved college or university for any work in the medical branches which he has successfully completed in his college course only so far as it is the full equivalent of corresponding work in the medical curriculum The holder of such bachelor's degree may also be given time credits of not exceeding one year, provided that such student has had at least 40 hours in physics, 144 hours in chemistry, 24 hours in osteology, 292 hours in human or comparative anatomy, 124 hours in histology, 85 hours in embryology, 145 hours in physiology and 46 hours in materia medica; provided that the applicant for such time credits satisfies the professors of the chairs mentioned in the medical school as to his proficiency in these first year medical studies, and satisfies the examiner, as provided for in Section 2, Article III, that his studies for which the degree was conferred include the above requirements Such student may be allowed to complete a course for the medical degree in not less than 31 months, provided he completes the remainder of the medical curriculum in that time

SEC 7—A college which gives less than a four years' course of study, but does not graduate students and is possessed of other required qualifications, may be admitted to membership

SEC 8—Each student shall be obliged to attend 80 per cent of the exercises in every annual course of study for which he seeks credit No student shall be given credit on examination unless he attains a grade of at least 70 per cent. or its equivalent in any other marking system And no student shall be graduated unless he shall have attained a passing grade in each and all subjects of the required curriculum

ARTICLE V

SECTION 1—The entire course of four years shall consist of at least 4.000 hours, divided into the subjects as shown in the following table, and no college shall be recognized that falls below this standard over 20 per cent in any one branch or over 10 per cent. in the total Laboratory or clinic hours may be substituted for didactic hours

CURRICULUM

	No of Hours of Lectures	Hours of Laboratory	Hours of Clinics	Total
Histology	30	60		90
Embryology	30	60	.	90
Osteology ..	30			30

University of Cincinnati, Cincinnati, Ohio; Miami Medical College, Cincinnati, Ohio; Cleveland College of Physicians and Surgeons, Medical Department Ohio, Wesleyan University, Cleveland, Ohio; Western Reserve University Medical College, Cleveland, Ohio; Ohio Medical University, Columbus, Ohio; Toledo Medical College, Toledo, Ohio; University of Oklahoma Medical Department, Norman, Okla.; University of Oregon Medical Department, Portland, Ore.; Willamette University Medical Department, Salem, Ore.; Western Pennsylvania Medical College, Medical Department Western University of Pennsylvania, Pittsburg, Pa.; Meharry Medical College, Medical Department Walden University, Nashville, Tenn.; University College of Medicine, Richmond, Va.; University of West Virginia Medical Department, Morgantown, W. Va.; Milwaukee Medical College, Milwaukee, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, Wis.

The secretary-treasurer of the Association is Dr. Fred C. Zapffe, 1764 Lexington Street, Chicago.

SOUTHERN MEDICAL COLLEGE ASSOCIATION.

The following requirements for admission to the freshman year are exacted by the colleges belonging to this Association:

SECTION 3.—He must possess a diploma of graduation from some literary or scientific institution of learning, or a certificate that he has passed the entrance examination to a university, or a certificate from some legally constituted high school. The minimum preliminary education required by the Southern Medical College Association shall be, after Jan. 1, 1906, a grammar school education and two years' successful attendance at a recognized preparatory school or a high school, or its equivalent, said equivalent to be determined by a superintendent of public instruction. A student may be given one month from date of his admission to submit his certificate of qualification. And if he fails to possess the requisite educational qualifications in one or more branches, he may matriculate and attend his first course of lectures, but must present the requisite certificate before matriculating in the second course, and all tickets or certificates issued in such cases must have the conditions printed plainly on the face of each.

The following colleges are members:

Medical Department University of Tennessee, Nashville, Tenn.; Medical Department University of Nashville, Nashville, Tenn.; Medical Department University of the South, Sewanee, Tenn.; Medical Department Vanderbilt University, Nashville, Tenn.; Medical Department Fort Worth University, Fort Worth, Texas; Medical College of Virginia, Richmond, Va.; Tennessee Medical College, Knoxville, Tenn.; Medical College of Alabama, Mobile, Ala.; Birmingham Medical College, Birmingham, Ala.; University College of Medicine, Richmond, Va.; Medical Department Baylor University, Dallas, Texas; Medical Department, University of Mississippi, Oxford, Miss.; Memphis Hospital Medical College, Memphis, Tenn.; Chattanooga Medical College, Chattanooga, Tenn.

The secretary-treasurer is Dr. G. C. Savage, Nashville, Tenn.

AMERICAN INSTITUTE OF HOMEOPATHY.

The minimum requirements for entrance into the freshman class of all homeopathic medical colleges, as adopted in 1901, are, with abbreviation, as follows:

COLLEGES AND MEDICAL GRADUATES.

By cities, arranged according to the population. (Population estimated by Census Bureau, 1903.)

City.	Population.	Number of Medical Colleges and of Graduates.											
		1901		1902		1903		1904		1905		1906

* With population of St. Paul figures would be 386,150.

† Kansas City, Mo., and Kansas City, Kan., are adjoining, and together have 228,412 population.

1. English Composition.—Exercise on assigned theme. not less than 200 words. Exercise in reading. Exercise in correction of ungrammatical sentences.

2. Mathematics.—Arithmetical exercises in (a) vulgar fractions, (b) decimals, (c) percentage, (d) proportion, (e) square and cube root, (f) weights and measures, (g) decimal system. Mensuration.—(a) Definition of terms, (b) exercises under the more fundamental rules.

3. Geography.—General facts about North America.

4. History.—General, with particular reference to human progress in art, science and letters. (The examination to avoid exact dates and minor details.)

5. Latin Language.—(a) Grammar, (b) four books of Cæsar or its equivalent.

The colleges recognized as in good standing by this organization are: Hahnemann Medical College of the Pacific; Denver Homeopathic Medical College; Hahnemann Medical College, Chicago; Hering Medical College; Homeopathic Medical Department of the State University of Iowa; Southwestern Homeopathic College, Louisville, Ky.; Kansas City Hahnemann

Medical College; Southern Homeopathic Medical College, Baltimore, Md.; Boston University School of Medicine; Homeopathic Medical College of University of Michigan; Detroit Homeopathic College; College of Homeopathic Medicine and Surgery of University of Minnesota; Homeopathic Medical College of Missouri; New York Homeopathic Medical College; New York Medical College for Women; Cleveland Homeopathic Medical College; Pulte Medical College, Cincinnati; Hahnemann Medical College of Philadelphia.

The secretary is Dr. Charles Gatchell, 100 State Street, Chicago.

NATIONAL CONFEDERATION OF ECLECTIC MEDICAL COLLEGES.

The following are the present minimum requirements for admission to colleges members of this Association:

1. Good English education, to be attested by (a) first-grade teacher's certificate, or (b) a diploma from a graded high school or literary or scientific college or university, or (c) regents' medical student's certificate, or (d) entrance examination covering a high school course including an elementary knowledge of natural history, physics and Latin.

2. Graduates from pharmaceutical, dental and veterinary colleges *may be* allowed one year's time on a four-year medical course only on condition that they comply with the entrance requirements and pass all examinations and perform all laboratory work embraced in the course of study of the freshman year. One year's advanced standing *may be* given students with degrees from a recognized literary college.

3. The course of instruction shall consist of a four-year graded course or its equivalent, as herein prescribed, including four sessions of seven months each in four different calendar years.

The following colleges are members of this Association:

American Medical College, St. Louis, Mo.; Bennett College of Eclectic Medicine and Surgery, Chicago, Ill.; California Medical College, San Francisco, Cal.; Eclectic Medical College of the City of New York, New York, N. Y.; Eclectic Medical Institute, Cincinnati, Ohio; Georgia College of Eclectic Medicine and Surgery, Atlanta, Ga.; Lincoln Medical College, Lincoln, Neb.; Kansas City Eclectic Medical University, Kansas City, Mo.

The secretary-treasurer is John K. Scudder, M.D., 1009 Plum Street, Cincinnati, Ohio.

State Boards of Registration

COMING EXAMINATIONS.

Wyoming State Board of Medical Examiners, State Capitol, Cheyenne, September 5. Secretary, S. B. Miller, Laramie.

Massachusetts Board of Registration in Medicine, State House, Boston, September 11-12. Secretary, Edwin B. Harvey, Boston.

Oklahoma Board of Medical Examiners, Guthrie, September 25. Secretary, J. W. Baker, Enid.

New York Boards of Medical Examiners, Albany, September 25-28. Chief of Examining Division, Charles F. Wheelock, Albany.

Illinois May Report.—Dr. J. A. Egan, secretary of the Illinois Board of Health, reports the written examination held at East St. Louis May 2-4 1906. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 136, of whom 114 passed and 22 failed. The following colleges were represented:

College.	Year Grad.	Number Examined.
PASSED.		
St. Louis University (Marion-Sims-Beaumont Med. Coll.)	(1905) 1; (1906)	55, 56
College of P. and S., St. Louis	(1906)	13
Barnes Med .Coll.	(1905) 1; (1906)	16, 17
Washington University	(1906)	26
Homeopathic Med. Coll. of Missouri	(1906)	1
American Med. Coll. of Missouri	(1906)	1
FAILED.		
Barnes Med. Coll.	(1903) 1; (1906)	6, 7
College of P. and S., St. Louis	(1906)	10
St. Louis Univ. (Marion-Sims-Beaumont Med. Coll.).	(1906)	5

Rhode Island July Report.—Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, July 5-6, 1906. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 30, of whom 23 passed, including 1 non-graduate, and 7 failed, including 2 non-graduates. The following colleges were represented:

College.	Year. Grad.	Per Cent.
PASSED.		
Yale University	(1898) 87; (1903)	82.3
Georgetown University	(1903)	75.1
Medical School of Maine	(1897)	76
Boston University	(1905)	75.9, 76.9
College of P. & S., Boston	(1906)	86.7
Harvard Univ. Med. School	(1904) 88.9; (1906)	78, 88, 88.6
Tufts Coll. Med. School	(1906)	79.3
College of P. S., Baltimore	(1902) 83.9; (1906)	75.1, 75.4, 81, 81.3.
College of P. & S., New York	(1906)	75.5; 83.1
Cornell University	(1905)	77.9
University Med. Coll., New York*	(1896)	75
Laval University	(1906)	79.4
FAILED.		
Maryland Med. Coll.	(1906)	61.5
Laval University	(1904) 65.8; (1905)	59.5, 62.7, 73.7

* Now the University and Bellevue Hospital Medical College.

Minnesota June Report.—Dr. W. S. Fullerton, secretary of the Minnesota State Board of Medical Examiners, reports the written examination held at St. Paul, June 5-7, 1906. The number of subjects examined in was 15; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 65, of whom 54 passed and 11 failed. The following colleges were represented:

PASSED.

* Failed to obtain passing mark in important branches.

The following questions were asked:

MATERIA MEDICA AND THERAPEUTICS.

1. What are the therapeutic uses of spiritus glycerylis nitratis? Give the symptoms produced in man by full therapeutic doses. 2. Distinguish between the following, by giving the officinal name and physical properties of each: (a) Mercurous and mercuric iodid; (b) Mercurous and mercuric chlorid. 3. Write a short description of serum antidiphthericum, giving prophylactic and curative dosage, frequency of dosage, and manner of using. 4. Outline the treatment of a case of syphilis after diagnosis is certain. (a) To what stage is mercury particularly applicable? (b) In what stage is potassium iodid most beneficial? (c) What do you understand by mixed treatment? To what stage is it best suited? Write a prescription for it. 5. Write a brief description of adrenalin, giving source, physical properties, physiologic action, field of usefulness and method of use. 6. What is hyoscin hydrobromid? Give its physiologic action, chief use, and dosage. 7. What is the principal alkaloid of physostigma? Name its official salts, with dose of each; its physiologic antidotes; its chief therapeutic use. 8. Give a safe dosage rule in prescribing for children. 9. Give the adult dose with frequency of repetition of the following: (a) acid hydrocyanic. dil.; (b) aconitin (crystalized); (c) fl. ext. gelsemium; (d) liq. potassium arsenitis; (e) sodium nitrite; (f) morphia acetate; (g) chloral hydrate; (h) sodium salicylate; (i) strychnia sulphate; (j) res. podophyllum. 10. Criticise the following prescription:

℞. Morphiæ sulphat ....gr. iii
Hydrarg. chlorid. corrosiv. ....gr. i
Potas. iodid. ....dram ii
Aq. pur. ....℥ii
Elix. simp. q. s. ad............................℥iii
M. Sig.: A teaspoonful in water three times a day.

HOMEOPATHIC MATERIA MEDICA.

1. Compare aconite, veratrum viride, gelsemium and ferrum phos. in febrile conditions. 2. Mention four of the most prominent remedies in the treatment of pneumonia and give indications for the use of the same. 3. Give indications for the use of sepia, graphites, arsenicum, mezereum and rhus in affections of the skin. 4. Name four of the principal remedies that may be used for whooping-cough and differentiate. 5. Compare sepia and pulsatilla; sepia and lilium tigrinum. 6. Give an outline of the use of rhus tox. 7. Give an outline of the use of cuprum metalicum. 8. Compare belladonna, glonoin and melilotus. 9. Differentiate belladonna, rhus tox., cantharis in facial erysipelas. 10. Name five principal remedies for coughs, with their indications.

SURGERY.

1. Colles' fracture—mechanism of origin, anatomic findings, symptoms and treatment. 2. Give in detail treatment of impending death from chloroform anesthesia. 3. Pes planus—symptoms, differential diagnosis and treatment. 4. Fracturæ colli femoris—symptoms subjective and objective, measurements, prognosis and treatment. 5. Describe briefly three (3) surgical diseases of the knee joint characterized by pain and swelling, and name three non-surgical diseases of the knee joint characterized by the same symptoms. 6. Differentiate in parallel columns between perforated duodenal ulcer; perforated typhoid intestinal ulcer and perforative appendicitis. 7. (a) Name ten (10) surgical diseases characterized by abdominal pain. (b) Name ten (10) non-surgical diseases characterized by abdominal pain. 8. Name five (5) surgical diseases peculiar to women characterized by abdominal pain and state briefly the treatment of each. 9. Panophthalmitis—causes, prognosis and treatment. 10. Give indications for enucleation of eye.

OBSTETRICS.

1. Describe the perineal body? What other structures constitute the pelvic floor. 2. Explain fully the mechanism of the second stage of normal labor. 3. Give principal causes of abortion, both local and constitutional; also prophylactic treatment for same. 4. How would you manage a case of transverse presentation with arm prolapsed? 5. What method do you advise to prevent laceration of the perineum? Describe fully its immediate repair in case of laceration.

DISEASES OF WOMEN.

1. Give causes and symptoms of acute ovaritis. 2. Describe fully a recognized operation for cystocele. 3. Give usual modes of infection and symptoms of general septic peritonitis. 4. Give symptoms of movable kidney; divide into subjective and objective. Treatment. 5. What are the most frequent local and general disturbances attending the menopause?

PHYSIOLOGY.

1. Locate and describe, and give function of kidney. 2. Same of cerebellum. 3. Same of parotid gland. 4. Give physiology of digestion of albuminoids. 5. Same of hydrocarbons. 6. Define and describe leucocytes. 7. Describe and explain normal heart sounds. 8. What is lymph; chyle; chyme? 9. Localize five centers in brain. 10. Trace the various steps in the development of an impregnated ovum.

CHEMISTRY, TOXICOLOGY AND URINALYSIS.

1. Give simple test for presence of sodium, potassium, strontium. 2. Give symptoms and treatment of carbolic acid poisoning. 3. Give sources, symptoms and treatment of ptomain poisoning. 4. Give two reliable tests for glycosuria. 5. Given a sample of urine to be analyzed, what would be your first procedure and what might you learn by it? 6. What is the signification of acetone in the urine? 7. What substances constitute the so-called "halogen group?" What is their leading chemical characteristic? 8. What do you understand by atomic weight? 9. What do you understand by chemical affinity? 10. How could you separate a mixture of oxygen and nitrogen?

MEDICAL JURISPRUDENCE.

1. Differentiate rigor mortis from the rigidity of hysteria and catalepsy. 2. How would you determine whether death was due to drowning or to some other cause and the body subsequently submerged? 3. To what extent is a physician protected by law in refusing on the witness stand to divulge the secrets of his patient? 4. What, in a medicolegal sense, constitutes malpractice? 5. What is monomania? Give two forms.

PREVENTIVE MEDICINE.

1. What precautions would you suggest to protect against whooping cough and measles during an epidemic? 2. What method would you suggest to insure pure milk supply for a community? 3. What measures would you adopt during a diphtheria epidemic to prevent contagion? 4. What is the cause of typhoid fever and where found? 5. What prophylactic measures would you recommend for the prevention of cholera infantum?

MEDICINE.

1. Give the symptoms, duration and prognosis of tubercular meningitis. 2. What physical signs warrant the diagnosis of aortic stenosis? 3. Contrast acute miliary tuberculosis with typhoid fever. 4. Define psoriasis. 5. What are the early symptoms of congenital syphilis? 6. Describe paralysis agitans. 7. What are the late symptoms of chronic interstitial nephritis, including urinary analysis? 8. What is the incubation period of scarlet fever, of typhoid fever, of diphtheria? 9. Give the formula for a single feeding of cow's milk modified for an infant of six months. 10 Describe the three commonest intestinal worms.

PATHOLOGY.

1. In a case of cerebral hemorrhage with convalescence, describe changes going on in extravasated blood and its effect on surrounding brain substance. 2. Describe briefly pathologic changes of

stomach, liver, kidneys and arteries produced by chronic alcoholism. 3. Describe the two pathologic stages of parenchymatous nephritis. 4. Describe the morbid anatomy of a case of osteomyelitis of tibia. 5. In a case of vesicular emphysema what are the pathologic changes of lungs and heart?

ANATOMY AND HISTOLOGY.

1. Describe the thyroid gland, anatomically. 2. Describe the formation of the brachial plexus and give its branches. 3. Diagram and name the lobes and fissures of the cerebrum. 4. What is the mediastinal space? Give subdivisions and contents of each. 5. Describe the suprarenal body anatomically. 6. Describe the Malpighian body histologically. 7. Describe the cornea histologically. 8. Diagram a section of a typical artery and name the structures. 9. Describe a red blood corpuscle and give the number per cubic millimeter in normal blood. 10. Describe the corpuscle of Vater or Pacinian body by diagram.

BACTERIOLOGY.

1. Name the different kinds of bacteria that may be found in case of suppurative otitis media. 2. Describe shape and characteristics of tetanus bacillus. 3. Describe mode of infection with malaria. Mention its exciting agent. 4. Describe your own process of disinfection of sick room after diphtheria. 5. What is the Widal test in typhoid fever?

Utah July Report.—Dr. R. W. Fisher, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, July 2-3, 1906. The number of subjects examined in was 19; total number of questions asked, 85; percentage required to pass, 75. The total number of candidates examined was 22, of whom 21 passed and 1 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent
College of P. & S., Chicago	(1906)	82. 93. 84. 85
College of P. & S., San Francisco	(1906)	89. 90
Northwestern Univ. Med. School	(1906)	81, 83
Rush Med. College	(1906)	87, 88
Hospital College of Med., Louisville	(1898)	83
University of Michigan	(1906)	85

Jefferson Med. Coll	(1906)	86, 86

FAILED.

St. Louis Univ. (Marion Sims-Beaumont Med. Coll.)	(1904)	61

* Second examination.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Erysipelas.

Erysipelas is not an infrequent infection, especially facial erysipelas. It begins most frequently as a primary lesion in the nose, gradually spreading to the face and the nearest glands in the neck. Within a space of a few hours the swelling may become so manifest as to close the patient's eyes and to cause the ears to swell out of proportion. Frequently the infection confines itself (and we say confines itself because no specific thus far has been found) to certain parts of the face, giving it the characteristic red, shiny appearance, or it may travel gradually to the scalp, neck and body. When the disease shows this tendency to travel it is very aptly called migratory. Just as this inclination to spread is rapid in its progress or slow, will the prognosis become more or less unfavorable, as the system will have more time to react and to eliminate the toxic material in the latter case and thus save the patient's strength.

A great deal has been written of the value of local treatment and the possibility of checking the extent of the infection by local applications or injections along the borders of the lesion. Other authorities place great stress on the value of internal treatment and at the same time express little confidence in local applications.

Locally, bichlorid of mercury dressings have been recommended in strength from 1 to 4,000 to 1 to 1,000. These dressings can not be applied properly to the face. The lead and opium lotion is recommended by some physicians, especially in those cases accompanied by burning and pain locally, and in some cases it has acted, seemingly, very efficiently. Iodin painted over the surface or around the edges is advised by some authorities, while others, still, recommend silver nitrate applied locally. With this latter preparation there is a possibility of injuring the epidermis, producing sloughing and a scar. The following combination, however, seems to be the most efficient local remedy:

℞. Ichthyoli		
Adipis lanolini hydrosi, āā	℥i	30

M. Ft. unguentum. Sig.: Apply locally and freely, followed by a dressing of plain sterilized gauze.

This preparation, owing to the absorption of the lanolin soon dries on the face, and consequently should be carefully washed off night and morning and a fresh dressing applied. While it is advisable to extend the ointment for a short distance beyond the diseased area, it does not check the extension of the infection. This combination, however, does seem to shorten the infection over the areas already involved, so that while new regions may be involved the older areas soon recover, and in a way this protects the vitality of the patient.

Osler is doubtful as to the value of internal treatment, but speaks of possible good being rendered by injections of solutions of bichlorid of mercury, carbolic acid, and the biniodid of mercury in strength of 2 per cent., a short distance beyond the border of the infection.

D. R. Brower, on the other hand, states that his experience has shown no value whatever in local applications, but he lauds the value of the tincture of the perchlorid of iron internally. He recommends this preparation in doses of twenty minims (1.30) each, at intervals of from two to three hours. At the same time, he emphasizes the value of whiskey in this infection, given in the form of eggnogs, five or six eggnogs a day, each containing one half an ounce (15.00) of whiskey.

It is probable that no medication has any value in cutting short the attack. Like pneumonia erysipelas is a self-limited disease, and the patient will recover if the system can be kept in a condition to withstand the effects of the poisons until the vitality of the organism has ceased.

Consequently, proper nursing is the keynote to success in such cases, by keeping the temperature down by bathing, and thus increasing the elimination, and likewise keeping the patient's strength up by proper nourishment. The circulation must be carefully watched, and if necessary strychnin or digitalis may be given for this purpose, administered in doses to meet the individual requirements.

Although the idea has been advanced that the field of infection may be limited by the local application of adhesive strips just beyond the borderline of the disease, experience has shown that such a procedure will not check its course, as the disease is spread through the subcutaneous tissue and not superficially over the surface of the skin.

Some authorities have advised applications of collodion for the same purpose, but its use has been without success. The value of such local measures have gained their unjustifiable reputations because, perhaps, the disease ceased to spread of its own accord simultaneously with such local applications.

The following combinations have also been suggested to be applied locally in the treatment of erysipelas:

℞. Guaiacoli	ʒss	2
Mentholis	gr. xv	1
Linimenti camphoræ	℥ii	60

M. Apply over the affected areas every two hours.

In strong, robust individuals pilocarpin is an old-time remedy, its value lying in its ability to promote elimination by the skin. It may be given as folows:

℞. Pilocarpinæ hydrochlor	gr. i	06
Sacchari lactis	gr. xii	75

M. Ft. cap. No. viii. Sig.: One capsule every six hours.

Or,

℞. Pilocarpinæ hydrochlor	gr. i	06
Aquæ	ʒiss	6

M. Sig.: Ten drops hypodermically every hour until free diaphoresis occurs.

Or,

℞. Liquoris plumbi subacetatis	f. ℥iii	90

M. Sig.: Add the entire amount to two quarts of warm sterile water and apply constantly on a soft cloth.

Radcliffe at one time stated that the following combination applied locally had almost specific properties:

℞. Ichthyoli	f. ʒii	8
Spts. etheris	f. ʒii	8
Collodii	f. ℥iiss	75

M. Sig.: To be applied locally.

Another combination suggested for local application is as follows:

℞. Plumbi acetatis
Ammonii carb., āā.......................ʒi 4
Aquæ rosæ.......................℥viii 240
M. Sig.: Apply locally on lint to allay the irritation.

Medicolegal

Malpractice Liability Same as for Personal Injury.

The Supreme Court of Washington says that, in the malpractice case of Froman vs. Ayars, where it holds there was sufficient evidence to support a verdict for the plaintiff for $5,000 damages for failure to properly treat a compound fracture of the bones of his left leg, about two inches above the ankle joint, counsel made an interesting argument to the effect that this case should be distinguished from one which is brought to recover for ordinary personal injuries, where the injury is wholly due to the neglect of the defendant in the case. It was argued that in this case the primary cause of the result which came to the plaintiff was the running away of the team, for which the defendant physician was in no way responsible, and that the degree of the latter's responsible relation to the final outcome could not be as great as that of one whose negligence laid the first foundation for the injury.

. The theory of the case, however, was that the final outcome to the plaintiff, by which he was deprived of a foot for the remainder of his life, would not have resulted if the defendant had properly applied his learning and skill. It was true, the plaintiff would have suffered pain and distress from the original injury, yet if the bones had properly united and the wound had healed, the suffering would have been but temporary, while as it was he must continue to suffer humiliation, inconvenience, and loss of earning power during the remainder of his life. If such a result would not have occurred but for the defendant's neglect, the court is not impressed that there was force in the logic of counsel's argument.

The defendant held himself as sufficiently skilled and learned to reasonably and properly treat the plaintiff's injury, and having undertaken to do so for a compensation, the duty was placed on him to bring to bear on such a treatment the reasonable and ordinary skill and care recognized by the members of his profession in general, as proper and necessary in such a case. He was neither required to exercise the highest grade of skill nor the highest degree of care, but only such as are recognized as ordinary and reasonable by the standards of his profession. The issue was made before the jury that he did not do this, and that his failure in that regard was the responsible cause of the final and serious result to the plaintiff.

Nor does the court think the award manifestly too large for a man 44 years of age at the time of the trial, the value of whose earning power should probably be viewed from the standpoint of a common laborer. His life expectancy at the time of his injury was admitted to be 26 years, and to pass through 26 years of life without a foot is a condition that it may be assumed no man, however humble his occupation, would be willing to accept for $5,000. There is seldom a case of this kind, or even one for ordinary personal injuries, when there does not seem to be some element of hardship either way the case may be decided; but such cases are triable by a jury and, when so tried, if there is reasonable evidence to support the verdict, it should not be reduced unless it is manifestly too large when all the facts and circumstances are considered.

Not Required to Provide Necessary Medical Attendance.

The Supreme Court of Oregon says that Miller vs. Beaver Hill Coal Co. was an action to recover for the breach of an alleged contract by which the company agreed to provide the plaintiff with necessary medical and surgical attention, at a hospital maintained by it, in case of his injury while in its employ. The evidence showed that the company had a hospital at its mine in charge of a physician at which its employés, and those of subcontractors paid through its office, were entitled to be cared for free in case of sickness or injury while in its service. For the support and maintenance of the hospital $1.50 a month was deducted from the wages of each employé by their consent, or at least without objection from them. The plaintiff, while at work for a subcontractor, was seriously injured by an iron splinter penetrating the abdominal wall. He was taken to the company's hospital and the wound examined by a physician temporarily in charge during the absence of the regular physician. The physician found the wound to be of such a character as to require a surgical operation which could not be performed by him alone or with the facilities at his command. He telephoned to the nearest town for assistance, but was unable to obtain a surgeon from that place and thereupon at the plaintiff's request telephoned to another place to a physician who went to the mine and performed the necessary operation. This physician charged the plaintiff $250 for his services, and, the company refusing to reimburse him therefor, this action was brought to recover the amount.

The court reverses a judgment rendered in favor of the plaintiff. It is of the opinion that the evidence fell far short of proving a contract by the company to provide the plaintiff with necessary medical and surgical attendance in case of injury. It says that the evidence merely showed that a certain sum each month was contributed by the plaintiff and his fellow employés, or exacted by the company, for the support and maintenance of a hospital for the use of the employés. There was no evidence that any statement or promise was made by the company to the plaintiff, or any of its employés, as to the object and purpose of the contribution or the benefit they would receive therefrom, other than that it was for hospital purposes. The transaction, therefore, under the testimony, constituted in law nothing more than a subscription by the plaintiff and the other employés for the charitable purpose of maintaining a hospital, where they could obtain such medical attendance and hospital accommodations as the fund thus subscribed would afford. A sick or injured employé was entitled to the use and benefit of the hospital and the medical services there provided, to the extent of the money contributed for that purpose, but he was not obliged to go to the hospital or to accept the accommodations. He could, if he chose, go elsewhere and employ physicians and attendants other than those provided by the company, and, if he did so, the company would not be liable to reimburse him therefor.

The only liability assumed by the company in collecting the fund was to expend it for the purpose for which it was subscribed, and no other. The mere fact that it received or exacted the contribution did not impose on it the absolute duty to furnish each contributor all the medical or surgical attendance that he might need or require, whether the fund provided was sufficient or not. The only duty of the company was to use ordinary care in the expenditure of the money and in the employment of physicians and surgeons in charge of the hospital, and it was not responsible for the negligence of the surgeon so employed in going away and leaving the hospital in charge of another.

Wills, Insanity in Ancestry, Suicide and Sanity.

The Court of Appeals of New York says, in the case of Roche vs. Nason, that the mere fact that a person came to his death by his own hand within a few days after he executed a codicil to his will did not justify an inference that it was drawn up or executed with suicidal intent. It says that we may guess or surmise that he contemplated suicide; but it is a matter of pure speculation, in the face of an equally strong probability that the thought of self-destruction never entered his mind until after the execution of the instrument. Moreover, it says that the fact that a person executes a will with this sin in contemplation does not necessarily imply any wrongdoing to be effected by his will. He disposes of his property after death as he might dispose of it during his lifetime. Again, the court says that there was testimony in this case from which it might be inferred that insanity had been manifested in the ancestry of the testator; but this proof would not properly lead to any inference of mental unsoundness on his part in the entire abtire absence of evidence tending to show any manifestations of mental derangement during his life of 37 years. Mental derangement can not be predicted solely on the circumstance that he killed himself. Insanity is not inferable from the mere act of suicide. Nor does the fact that a man has taken his own life, alone and of itself and in the absence of any other evidence as to his mental condition, warrant the deduction that his mind was unsound at the time of the suicidal act, or prior thereto, or that he lacked testamentary capacity, for human experience has often shown that sane men have taken their own lives.

Medical Record, New York.

August 11.

1 *Does the Drinking of Water Give Typhoid Fever? R. C. Eccles, Brooklyn.
2 *Proper Limitations of the Medical and Surgical Treatment of Gastric Ulcer. G. W. McCaskey, Ft. Wayne, Ind.
3 Health and Mortality of the Cotton-Mill Operatives of Blackburn, England. F. S. Crum, East Orange, N. J.
4 Puerperal Types of Sepsis. W. S. Stone, New York.
5 *Study of Seventy Cases of Brain Tumor. A. C. Brush, Brooklyn, N. Y.
6 *Air Dilatation in the Treatment of Chronic Constipation. L. J. Hirschman, Detroit.
7 *Treatment of Injuries to the Extremities by Mechanotherapy. W. O. Rau, New York.

1. **Does Drinking of Water Cause Typhoid.**—Eccles declares that there is no reasonable room to doubt that the development of typhoid fever is connected with the use of infected water; but that typhoid fever results from the drinking of infected water is quite a different proposition. He then emphasizes the important part which flies play in carrying disease germs to food. It is easy to see how food may multiply disease germs to the danger point, but it is not evident, he declares, how any person could take the disease from water that thousands are drinking without the slightest injury.

2. **Treatment of Gastric Ulcer.**—McCaskey believes that every case of gastric ulcer ought, if possible, to have the benefit of careful medical treatment by an intelligent practitioner before the question of surgery has been considered at all. At the outset the case is medical, not surgical. There is no hard-and-fast rule by which the precise length of time can be decided during which medical treatment should be followed in intractable cases before surgical intervention is sought. Each case should be considered in its entirety. Repeated systematic, scientific study of stomach secretion and motility and the material obtained from the fasting stomach are of the greatest value to the physician who has the patient under his care.

5. **Study of Seventy Cases of Brain Tumor.**—Brush states that in twenty of his cases the most prominent early symptom was convulsive seizures. Next to such disorders defective vision was the most common early symptom for which the patient sought relief. Of his cases fourteen patients recovered under medicinal treatment, nineteen were improved by surgical means, thirteen died, twenty-six passed from observation as unimproved and eight are still under observation.

6. **Air Dilatation in Chronic Constipation.**—Hirschman believes that the direct stimulation of the atonic sigmoid and rectum by means of mechanical dilatation up to the present time has given the best results in cases of chronic constipation. He describes his simple pneumatic dilator for accomplishing this distension. In consists of a rubber bag with a stem, which is slipped over the distal end of a Wales bougie, No. 3-5, this bougie being canaled. Compressed air at a low pressure is allowed to enter the bag slowly and distension to any desired extent is produced. A cut-off valve easily regulates the distension. Instead of the compressed-air apparatus an ordinary atomizer bulb or a small bicycle pump may be used. The patient is placed in the Sims position for the treatment. This is repeated daily for from five days to a week. When defecation approaches the normal treatments are given on alternate days. The interval is gradually lengthened.

7. **Mechanotherapy.**—Rau speaks of the advantages of mechanotherapy in the treatment of injuries to the extremities. He describes the arthromotor and believes that its introduction is an important step forward in this field of treatment. This apparatus combines in one machine everything necessary for the treatment of the extremities. It gives passive as well as active movements, and can be fitted for every joint of the extremities. It can be regulated to go from the shortest to a full normal movement, and so as to begin a movement at any angle. Treatment is absolutely painless. In connection with the mechanical treatment, massage and, if possible, local application of heat should always be resorted to. The results of treatment in many cases have been very encouraging. Rau thinks that this treatment, when properly given, will greatly lessen the period of idleness following injuries to the extremities.

8. **Uterovaginal Drainage in Puerperal Fever.**—Gallant reports six cases in which use was made of his bivalve uterine drain with most excellent results.

9. **Function of Suprarenal Glands.**—Davis believes that we are warranted in concluding that an excess of epinephrin is a causative factor in the production of artero-capillary fibrosis and atheroma. He also calls attention to an unrecognized etiologic factor in the production of disease of the vascular system, namely, the sexual function. His attention was directed to this, he says, while studying the embryology and histology of the suprarenal gland. Its embryologic source and the arrangements of muscle fibers in the walls of the veins and the sinuses are suggestive of an erectile tissue and close relation to the generative apparatus.

11. **Chronic Atropin Poisoning.**—Tyrrell reports the case of a man who, because of a slight cloudiness in the center of the cornea, the result of the application of a caustic, or of granular lids, made use of a solution to make the pupil larger, so that he might see around the scar. He used this solution for fourteen years with good effect, so far as his eyes were concerned, but with disastrous results to his health. Under an appropriate treatment the patient made a complete recovery.

13. **Significance of Occult Hemorrhages in Stomach Affections.**—The observations of Friedenwald and Rosenthal agree in every respect with the conclusions arrived at by other investigators. Occult blood was not found in 92 examinations in 47 cases of chronic gastritis; in 42 examinations in 15 cases of atony of the stomach; in 108 examinations in 42 cases of hyperchlorhydria; in 21 examinations in 8 cases of hypersecretion; in 16 examinations in 9 cases of acute gastritis; in 57 examinations in 25 cases of nervous dyspepsia. So significant is the fact that they have frequently been enabled to rely on the constant absence of this sign as evidence sufficient to exclude the presence of ulcer and cancer, and on the other hand as evidence in favor of the presence of either a gastritis or some form of gastric neurosis.

Thirty-five cases of ulcer of the stomach were examined as to the presence of occult blood in the stools. This condition was found in 26, or 74 per cent. It was not noted, however, at every examination; most frequently, however, before the patient had been placed under treatment and when the pain and nausea were extreme; after the patient had been served in normal rats of the same age. On a third rat ticks were fed and the parasites appeared in the peripheral circulation after five days, the usual incubation period.

14. **Gallstones Passed by Rectum.**—The main interest in the case reported by Dickson lies in the fact that three gallstones of large size were evacuated from the gall bladder by natural means. They had evidently ulcerated through the fundus of the gall bladder into the large intestine, after these two organs had become attached to each other by adhesions, then passed slowly down the large intestine, and became surrounded by a mass of feces, causing partial obstruction of the bowels which was relieved by the repeated use of large enemata. The stones when fitted together made a mass 3½ inches long, forming a complete cast of the interior of the gall bladder. That they passed down by the cystic and common bile ducts is very improbable, there having been no severe attack of jaundice, and moreover the stone which formed a cast of the fundus of the gall bladder was the first to appear in the rectum, and preceded the others by about four months. Ulceration into, and passage by way of, the small intestine is also excluded by the clinical history, and stones of such large size, if they had traveled by the last-named route, would almost certainly have become impacted at the ileocecal valve. A small ischiorectal abscess formed a few days after the first stone was passed, probably from fissuring of the stretched mucous membrane of the anal canal and infection with organisms. This was opened—about one and a half ounces of pus being evacuated—and rapidly healed up; the patient is now in good health. The three stones, after drying, weighed 1.71 ounces.

20. **Hallucinations from Starvation.**—Lassignardie's thesis in 1879 (Bordeaux) was devoted to the psychic disturbances consequent on deprivation of food. His conclusions were to the effect that fasting promoted the development of the intellectual faculties, especially the imagination. In actual starvation the character changed and became irritable and cruel, with loss of memory and will power, and development of hallucinations, agreeable or distressing. He has recently been studying the miners who were buried for so many days in the mine at Courrières. One miner was not released until after an interval of 25 days. He frequently imagined himself at home and talked with his wife and imagined that he found scraps of bread, which he ate with relish. Like most of the others, he frequently imagined that he saw bright lights before him. All the miners said that they became very irritable and frequently quarreled. They all had hallucinations, generally agreeable, but nearly all retained their reason, only a few being actual dupes of their imagination.

21. **Radical Treatment of Inguinal Hernia.**—The points in which Savariaud has modified the Bassini technic are in the restoration of the abdominal wall and in the shortening of the spermatic cord in case of a varicocele or lipoma in the cord. The article is illustrated.

23. **Sensory Aphasia.**—Dejerine presents evidence to confirm the assumption that disturbances in speech and mental disturbances are due to entirely different processes.

27. **Sterile Catgut, Ready for Use.**—Karewski sterilizes the catgut in a special glass vial, open at both ends, in the fumes of boiling 70 per cent. alcohol. The vials are exposed for an hour to the fumes at a temperature of 78.8 or 81 C. The catgut is wound by a yarn-winding machine and is boiled first in glycerin, then extracted cold in ether and alcohol. Each vial is partly filled with alcohol, containing from 1 to 3 per cent. glycerin, and is heated again to 103 C. for an hour. The open ends of the vials are then fused and they are kept in a vessel of alcohol ready for use. Tests with anthrax spores showed that they are destroyed by this method of sterilization. The vials have a small neck with a bulging part above, terminating in a long narrow tip. The end of the catgut is drawn out through this long top of the vial, a knot in the catgut preventing its slipping back, the knot fitting into the bulging part. The vial is opened by breaking the neck just below the bulging part. The article is illustrated, showing the special contrivances for large clinics and for hospital use.

35 *Balneotherapy in Gynecologic Affections.—Badekuren bei Uterusmyomen und exsudativen entzündlichen Erkrankungen der weiblichen Geschlechtsorgane. L. Nenadovics.

28. **Experimental Research on Balneotherapy.**—Heinsheimer has been studying on dogs with Pawlow fistulæ the effect of various mineral waters, bitters, etc., on the secretions. The results harmonize with those observed in the clinic.

30. **Influence of Domestication on the Origin of Diseases.**—This article was presented as one of the principal addresses at the Lisbon International Medical Congress and was mentioned in the notice of the congress in the last volume of THE JOURNAL. As examples of the degeneration that follows domestication, von Hansemann mentions that neurasthenia and hysteria are frequently observed among animals. He states that he knows of instances of imaginary gestation in the dog. The abdomen became enlarged, the milk glands swelled, and colostrum was secreted, the same as in an imaginary human pregnancy, and all the signs subsided after the normal term of gestation. He also mentions a dog that was given injections of morphin daily for a time on account of an operation. After the injections were discontinued the dog suffered from attacks of pain every day at the hour of the injections, but he quieted down at once if a little water was injected in place of the former morphin. Mental disturbances occur among uncivilized peoples, but the persons thus affected are soon exterminated and do not propagate and perpetuate the neurotic tendency. The increasing numbers of neuropathic individuals parallel the progress of civilization, and might even be used as a criterion of the stage of civilization in a special land. Animals in liberty and untrained children do not eat more than appetite calls for, but domesticated animals and children, tempted to eat by savory viands, soon acquire the habit of eating more than they require. In respect to tumors he remarks that wild animals and uncivilized human beings seldom live to reach the cancer age, which may explain the rarity of cancer among them. Tuberculosis in persons occupied in dust-laden air does not affect the apices. The tuberculous lesions are found where the inhaled dust is most accumulated. This form of tuberculosis is most certainly a "domestication affection." The same might be said of ordinary tuberculosis affecting a person changing to different conditions of life. Japanese students in Germany are liable to acquire tuberculosis, as also German students in Japan, showing the importance of a changed manner of life in the origin of the disease. This fact is also evidenced by the frequency of tuberculosis in prisons, etc. True gout is a typical example of a "domestication affection," he thinks. He has never known of its occurrence spontaneously in animals or among uncivilized peoples, and the same can be said of rachitis. The latter is never found

among people living in the open air or in well-ventilated houses who keep the children out of doors and refrain from bundling them up much in infancy. In conclusion he mentions the evil effects of wearing deforming shoes, corsets and hard hats as "domestication affections."

33. **Serpiginous Ulcer of the Cornea.**—Helbron urges promptness in treating ulcer of the cornea, as many eyes are still lost every year from progressing hypopyon-keratitis. Antipneumococcus serum is a valuable adjuvant, but can not be relied on exclusively, he thinks. He believes in applying the galvano-cautery even in the very earliest stages, using it at a low red heat, so as not to destroy the sound cornea beneath in the incipient cases, supplementing it with perforation and cleansing out the ulcer excavation in severe cases. Boric acid or sublimate salve afterward, he states, is more effectual than iodoform.

34. **Retained Enemas.**—Pollatschek uses small enemas of 50 or 100 or 150 gm. of Carlsbad waters at a temperature of about 50 C. in the treatment of chronic diarrhea. The infused fluid is retained and the procedure is repeated until the patient is able to retain the enema. He has found these small, hot enemas a very reliable palliative and curative measure. Boiled water and salt solution have also been found useful by his patients after their return home, but he has no personal experience except with the Carlsbad Sprudel water.

35. **Balneotherapy in Gynecologic Affections.**—Nenadovics reviews what has been written on this subject and his own experience, all tending to show, he thinks, the value of balneotherapy in gynecologic affections as soon as the febrile stage is past and the patient is able to travel. The ability to travel depends on the absence of fever and the general condition; the local pain and tenderness may be disregarded in cases with exudation and inflammatory processes. Mud baths, he states, are especially useful in case of uterine myomas in young women of delicate constitution, debilitated from hemorrhages, and also in chlorosis.

38. **Diagnosis of Congenital Atresia of the Small Intestine.**—Walz describes the postmortem findings in a case of atresia of the small intestine associated with horseshoe kidney, and shows that the atresia is due to embryonal malformation. Meconium can be passed even with complete atresia of the duodenum. In every case of continuous vomiting by a newborn infant the meconium should be histologically examined, as operative treatment of atresia of the duodenum can count on success only if done early. If there is no spontaneous passage of meconium, then some can be obtained with an enema. Entire absence of lanugo hairs in the meconium, he states, is a positive sign of complete occlusion of the duodenum before the fifth month of embryonal development. This diagnosis is strengthened by the absence at the same time of pavement epithelium and of elements of food (droplets of fat).

43. **Active Immunization Against Infectious Diseases.**—This communication was the summarizing report on this subject, read at the Lisbon International Medical Congress.

44. **Cultivation of Typhoid Bacilli from Coagulated Blood.**—Fornet states that he was able to cultivate typhoid bacilli from the blood in 14 out of 19 cases of typhoid fever long before the agglutination test gave positive findings. The bacilli in unmodified blood all died, either from the bactericidal power of the blood or from the mechanical injury from the fibrin network. When bile is added to the blood it breaks up the fibrin network and releases the bacilli, so that they can be cultivated from the blood afterward. The clot of blood left from the agglutination test is placed in a test tube with about 5 c.c. of bile from the slaughter house and put in the incubator over night. A very small amount of blood is sufficient for the purpose.

45. **Improved Formalin Technic for Biologic Test.**—The great difficulty with the Uhlenhuth-Wassermann biologic precipitation test has always been the rapid spoiling of the blood and meat extracts, and the necessity that the material with which the animals are injected must be sterile. This difficulty can be obviated by adding formalin to the extracts. Loele found that the best mixture for the purpose was 2 per cent. formalin and 0.6 per cent. sodium chlorid in distilled water. This is mixed half and half with the blood to be injected into the rabbit to produce the prepared serum. The mixture found most effectual for preserving the extracts of blood and tissues was 75 parts of distilled water, 15 parts of calcium bichlorid (1 per cent. solution in distilled water); 10 parts of magnesium chlorid, and 1 part formalin. Precipitation occurs with remarkable distinctness with this alkaline formalin mixture.

47. **Rest in the Open Air for Gallstone Patients.**—Fink proposes to have erected at Carlsbad a "reclining hall" (Liegehalle) for gallstone patients, for whom rest and warmth to the abdomen for an hour or two or longer daily have been ordered. He believes that those suffering from cholelithiasis thrive much better when they spend the entire afternoon lying down, with very little exercise in the mornings. He would like *to have open shelters provided, as for the tuberculous, and the* Carlsbad authorities are now discussing ways and means to carry his proposal into effect.

49. **Metabolism in Leukemia Under Roentgen Treatment.**—This long article concludes with a warning that the general condition should be watched carefully and Roentgen treatment be suspended, notwithstanding a progressive reduction in the leucocytes, if anything indicates that the action of the Roentgen rays is going beyond the desired effect. The number of reds and the proportion of hemoglobin must be supervised, and also the elimination of uric acid. If the latter shows no signs of reduction, this must be accepted as a signal for special caution.

Therapie der Gegenwart, Berlin.

Last indexed, page 467.

50 (XLVII, No. 4.) Present Status of Cancer Research.—Der heutige Stand der Krebsforschung. H. Apolant.
51 *Zur Behandlung hartnäckiger Ischias-Fälle mit perineuraler Infiltration (sciatica). Umber.
52 *Zur Behandlung der chronischen Verstopfung (obstipation). O. Kohnstamm.

55 Zwei Fälle von chronisch-ankylosierender Entzündung der Wirbelsäule (spine). R. Zuelzer.
56 Zur Diagnose und Therapie des chronischen Dickdarm-Katarrhs (of large intestine). W. Zweig.

51. **"Infiltration" Treatment of Sciatica.**—Umber has had excellent results in 14 cases of chronic, long rebellious sciatica treated with perineural injections by a modified infiltration technic. He injected from 70 to 100 c.c. of a 1 per thousand solution of eucain with 8 per thousand sodium chlorid. Nine patients were cured completely by a single or once-repeated injection. One, a syphilitic, was only slightly improved. In another patient paresis of the peroneus developed tardily after the one effectual injection. In some cases slight twinges were felt later in the peroneus region, but they subsided after a small amount of the fluid had been injected at the sensitive

point (30 c.c.). It was truly remarkable, he says, to see patients walking about entirely free from pain the day after the injection, when up to that time they had suffered continuous agony unmodified by any treatment. The last four patients were injected with physiologic salt solution alone, without the eucain, and the results were exactly as good as with the anesthetic. He injected a little larger quantity, up to 170 c.c. A single injection of this kind was followed by complete relief from pain in forty-eight hours. This latter technic is so simple and free from any danger that he advocates it for general adoption, instead of the eucain for fear of encountering an idiosyncrasy to this drug. He cites a case on record of death from 0.08 gm. of eucain. Lange of Leipsic, was the first to practice this "nerve infiltration," as was mentioned at the time in these columns, page 586 of vol. xliv.

52. **Treatment of Constipation.**—The principal features of Kohnstamm's successful treatment are the avoidance of meat and the ingestion of milk three times a day at least. He believes that worry has a constipating effect, and that the focussing of the will power is liable also to have an inhibiting influence on the visceral functions.

71 *Sulla formazione e sul valore semeiologico del muco e delle muco-membrane. A. Riva.

58. **Trypsin in Treatment of Cancer.**—Zanoni has been repeating Beard's experiments with pancreatic ferment in the treatment of cancer. His results were likewise positive; the parts of the cancer in contact with the ferment became destroyed; granulations from the ear, and nasal polyps placed in the ferment in a test tube were rapidly digested. A superficial mammary mouse cancer became hollowed out under the influence of the trypsin, but without pain and without eschar formation. In proportion to the amounts injected into the mouse tumors, it would be necessary to inject a human being with 177 c.c. for a weight of 70 kg.

59. **Etiology of Rabies.**—Materazzi's researches confirm those of others, sustaining the etiologic importance of the Negri bodies in rabies. They can be detected and the diagnosis confirmed in 24 hours, he says, by simple microscopic examination of the fresh hippocampus, and with a minimal amount of material.

60. **Epidemic Pneumonia.**—De Blasi has observed an epidemic of pneumonia, affecting 60 persons, mostly in groups, and the disease displaying a marked contagious character. A pleural effusion was evident in about half the cases, but it was never purulent.

61. **Yellow Patch in Palms and Soles in Typhoid.**—Philipovicz regards the yellowish discoloration of palms and soles as pathognomonic of typhoid fever. In one of Minciotti's patients the yellow patches were painful. The symptom was most marked in the left palm and sole. The tint was a pronounced orange, and gradually subsided to normal. The pain first attracted attention to the left sole about the eighth day of the disease.

66. **Ligature of the Innominate Artery.**—Giordano's technic aims to open up the field extensively while respecting the points of attachment of the muscles of the region. It has shown many points of advantage over the ordinary technics in his tests on the cadaver. The sternum is divided with the wire saw introduced beneath, sawing on a level with the second rib. The clavicle is then sawed in the same way. The incisions and sawing outline a bone-muscle-skin flap, shaped like a trapezoid, which, when lifted up, exposes amply the innominate artery.

68. **Syphilides of the Liver.**—De Renzi discusses a case of syphilitic, interstitial hypertrophic inflammation of the liver, with chronic icterus. Marked improvement followed mercurial treatment. The icterus had been the first symptom, appearing eighteen months before. The liver, spleen and some of the glands became gradually enlarged. There was no alimentary glycosuria; the functions of the liver were evidently retained and exaggerated. The patient had long lived in a malarial region.

71. **Membranous Enteritis.**—Riva regards hypersecretion of mucus as a means of defense on the part of the organism to protect the mucosa lining the intestinal canal. He has found that bile has an anticoagulating action on the mucus, and has a curative effect in case of hypersecretion of mucus with accumulations of mucous casts in the stools. The mucomembranous formation is probably due to increased production of mucus with simultaneous reduction of anticoagulating substance, and is generally the expression of inflammation of the gastrointestinal mucosa. Its action is injurious, as it obstructs the free course of the feces and provides nooks and recesses where microbes and toxic substances can accumulate. He uses a special preparation of bile and has found it useful in treating cases of mucomembranous enteritis, as he previously reported.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

PROPHYLAXIS AND TREATMENT OF INTERNAL DISEASES, Designed for the Use of Practitioners and of Advanced Students of Medicine. By F. Forchheimer, M.D., Professor of Theory and Practice of Medicine and Clinical Medicine, Medical College of Ohio, Department of Medicine of the University of Cincinnati, etc. Cloth. Pp. 652. Price, $5.00 net. New York: D. Appleton & Co., 1906.

OPERATIVE TREATMENT OF PROLAPSE AND RETROVERSION OF THE UTERUS. By J. I. Parsons, M.D., M.R.C.P., M.R.C.S., Physician to the Chelsea Hospital for Women, Late Surgeon Royal Maternity Charity, Fellow of Royal Medical and Chirurgical Society, Obstetrical Society of London. Addresses

THE DISTRIBUTION OF AFFERENT NERVES IN THE SKIN.[*]

PROF. MAX VON FREY,

WÜRZBURG, GERMANY.

While the question as to how the ventral roots of the spinal nerves are engaged in the innervation of the muscles is in its main features cleared up, especially through he researches of Sherrington,[1] our insight into the disribution of the afferent fibers is still very incomplete. Here again the work of Sherrington represents by far he most important contribution, his experiments being he more interesting because of their having been made mostly on monkeys.

Sherrington[2] determined the extent of the cutaneous areas of the dorsal roots of all the spinal nerves and found that these areas are always continuous for each single root and that they overlap to a considerable extent. His method of observation was that of remaining anesthesia, as Head has termed it. The skin field of a spinal root is isolated by dividing as many adjacent roots as is necessary to surround the skin field in question by a totally anesthetic zone. By pinching the skin and watching the reflexes thus called into action the borders were defined.

This way of proceeding neglects the functional differences of the afferent fibers, and its results are, therefore, applicable to the sensory disturbances in man only with certain restrictions. Sherrington[3] tried to make up for this deficiency by a series of experiments on tame monkeys, cutting one or more of the dorsal roots and examining the field, thus rendered anesthetic or hypesthetic, with a variety of stimuli. He generally found the heat-sensitivity and the pain-sensitivity more impaired than the tactual sensitivity, which means that "the pain-field and the heat-field of a single sensory spinal root, at least in the case of certain spinal nerves, are less extensive than is the touch-field of the same root." He recognizes that the problem is but imperfectly accessible by researches on animals and awaits fuller information from the study of clinical cases.

In dealing with sensory disturbance in man after injury to cutaneous nerves, the first thing to be considered is what kind of sensations belong to the normal skin and to the underlying tissues. The subject has been treated by a large number of physiologic and psychologic investigations, and I propose, so far as I am able, to draw a short sketch of their issue.

Most physiologists agree that the sensory functions of the skin are based on four fundamental qualities mediating the sensations of warmth, cold, touch and pain. Careful investigations have placed it beyond doubt that corresponding to these functions the nerve-supply to the skin must be a fourfold one. Blix was the first to note that the sensibility of the skin to warmth, cold and touch varies widely within a given area, provided the stimuli act on a very small part of it. He ascribed this fact to the existence within the skin of terminal organs of specific function, and he regarded the most irritable points as their projection on the surface. Goldscheider has confirmed and amplified the conclusions arrived at by Blix, but was often misled in his observations by not using quantitative methods. Later I was able to show that the spots most sensitive to touch had a peculiar relationship to the hairs, lying always on the windward side of the hair and covering its root or sheath.[4]

The position of these touch-spots once ascertained, it is easy to prove that they react in a specific way to various kinds of stimuli. In using, for instance, the head of a pin as an electrode, the touch-spots respond to an alternating current of minimal strength by a vibrating sensation very similar to that evoked by a tuning fork brought in contact with the skin. In the spaces between the touch-spots no such sensation is provoked, but the same current or even a weaker one is felt as a non-vibrating, permanently painful prick.

We have, then, two different sensations evoked by the same minimal stimulus, and it depends on the place where the stimulus is applied as to which one is produced. The most probable explanation of this fact is that the effect depends on the kind of terminal organ excited by the stimulus. The one reacts quickly enough to transmit separately the rapid alternations of the current; the other, too slow to do so, is kept by them in a condition of constant irritation. In what part of the nervous system this difference of reaction is seated, whether in the nerve fibers, in the terminal organs, in certain central parts or, as seems not improbable, in all three of them, can not be decided at present. But it is clear that the nervous impulses belonging to the two sensations must be transmitted to the brain by different paths, a conclusion which quite agrees with clinical observation.

As regards the temperature sensations, similar circumstances prevail. If the skin is examined with bits of wire, kept at temperatures a few degrees above or below the temperature of the skin, it is easy to map out a large number of cold-spots and a more restricted number of warm-spots. They represent minute, but unchanging areas on the skin, in which the sensation cold or warm is aroused by a minimal stimulus, that is to say, by a stimulus not felt in the intermediate spaces.

In applying thermal irritants to these points generally only one kind responds. If the temperature of the skin is lowered the cold-spots are stimulated; if it is raised the warm-spots come into play. It is impossible to give definite temperatures as liminal values, since the physiologic zero point changes, not only as regards time, but also in different parts of the skin, as, for instance, in passing from the volar side of the hand to the dorsal one, or from the covered parts to the uncovered ones and so on. Some stimuli act on both the warm and the cold-spots. Mechanical and electrical irritations have this power and under certain circumstances thermal irritation also. With temperatures between 45° and 50° C. one is generally sure to stimulate not only the warm-spots, but also the cold-spots, evoking from the latter a sensation of cold, which I have termed the paradoxical cold sensation. It is, therefore, quite possible that one and the same stimulus is felt both as warm and cold. This can be conveniently shown in the following way: By means of a small lens the sunlight is concentrated on a part of the skin where the warm and cold-spots have been determined beforehand. By bringing the focus to a warm-spot the sensation of warmth is produced, on a cold-spot the sensation of cold. In the intermediate spaces the concentrated light is either felt as painful or is not felt at all, according to its intensity. The touch-spots never respond, being not accessible to any kind of thermal stimulus. The experiment shows in a very striking manner the specific nature of the afferent nerve-fibers of the skin.

---

[*] Address before the Section on Pathology and Physiology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

[3] Jour. of Physio., 27, 360, 1892.

[4] Abtr. Ges. d. Wiss, Leipzig, 1896, 23, 175.

From this and other observations the conclusion may safely be drawn that the nerve-supply to the skin is a fourfold one. To use a rather schematic but illustrative expression, it can be said that the surface of the skin is divided into a very large number of minute areas or patches, each of which represents the field of distribution of the nerve fibers belonging to one or other of the above named four qualities. According to a rough estimate, there are on the skin of the trunk and limbs about 30,000 warm-spots, 250,000 cold-spots and half a million of touch-spots. As to pain, reliable determinations are wanting. It is easy to prove that the sensibility to a painful stimulus passed across the skin varies considerably from place to place, but it is difficult to mark out with the same exactness as can be done for the three other sensations, spots of maximal sensibility. The reasons for this deficiency are manifold, one being, no doubt, the richness of the skin in nerve fibers of this sort.

I have often been told that common experience contradicts the conception of the nervous supply of the skin as here sketched, in that a warm, a cold, a blunt or a sharp object passed over the skin is everywhere recognized in its proper qualities, and that the sensation seems a continuous one throughout. In granting that the afferent nerves are nowhere mingled into a homogeneous or uniform layer and that the surface of the skin is, so to speak, checkered by a variety of terminal organs, the expectation is naturally raised that an object moving over the skin ought to provoke a sensation varying in quality and changing in intensity. I have given already a few instances which prove that this expectation is by no means an erroneous one. If the moving object is of very small size and its stimulating power not far above the threshold value, the sensation is in very fact a discontinuous one, varying generally both in intensity and quality. Besides there are to be found in every normal skin regions where one or two of the typical sensations are wanting, where cold is felt but not warmth, pain but not touch, and *vice versa*.

Still, the objection just raised holds good under the usual circumstances and must be somehow accounted for. I think the explanation lies in a peculiarity, belonging to all sensory organs, which for the sake of convenience I shall term the irradiation of stimuli. There are two kinds of irradiation, a physical and a physiologic.

Physical irradiation consists in the spreading of the irritation over a larger number of terminal organs than the nature of the stimulus itself would seem to demand. This spreading is caused by certain physical qualities of the tissues or parts conducting the stimulus to the terminal organs, as, for instance, by the imperfections of the dioptric apparatus in the eye, by the diffusion in the saliva of the substances affecting taste, etc. In the skin, thermal differences and mechanical deformation are apt to spread to a considerable extent, with the effect that, unless special precautions are employed, nearly every stimulus is sure to irritate more than one terminal organ. This circumstance explains the difficulty or inexpediency of mapping out touch-spots or temperature-spots over such parts as possess a thick epidermal layer, as the volar side of the hand, the sole of the foot, etc.

Of far greater importance is the phenomenon to which I have alluded as physiologic irradiation. The points of a pair of compasses set on the skin are not discriminated as separate if the distance is reduced to a certain liminal value, which differs widely in various parts of the skin. This fact was recognized by E. H. Weber, who used it as a means to measure the acuteness of local discrimination. His conception was that the liminal distance had an anatomic bearing in that it depended on the distribution and ramification of nerves in the skin. This view had to be abandoned after several investigators had found that the liminal distance could be much reduced in applying the two stimuli not simultaneously but successively. In using this device and choosing a suitable time-interval between the two stimuli, I was able to show that any two neighboring touch-points may be discerned, though it is not possible under these circumstances to judge their relative position.[5]

The enormous differences between the liminal distances found in simultaneous and successive stimulation can not be explained on an anatomic basis, but point to a difference in the spreading of the irritation, being evidently facilitated by simultaneous stimulation. This is proved, moreover, by the fact that simultaneous irritation of two neighboring touch-points is always felt more strongly than that of a single one, which means that the two irritations are added, one to another, as is the case with stimuli successively applied to the same terminal organ. It is, therefore, right to say that the localization of a given stimulus and the intensity with which it is felt depends not only on the physical properties of the stimulus and on the number and quality of the terminal organs engaged, but also on the conditions existing in the central nervous system.

I wish to lay special stress on this point, since it helps to clear up some very interesting observations recently recorded by Dr. Head.[6] In order to study the consequences of nerve injury more accurately than was possible on the patients of the London Hospital, he submitted himself to a very heroic and at the same time very valuable experiment. In April, 1903, the external and radial cutaneous nerves of his left forearm were divided in the neighborhood of the elbow, and after small portions had been excised the ends were united by silk sutures.

---

[5] Würzburger Sitzungsber., 1899 and 1902.

[6] Head, H.: The Afferent Nervous System from a New Aspect, Brain, 1906, vol. ii, p. 99.

Dr. Head describes the consequences of the operation in the following way: "It produced loss of all forms of cutaneous sensibility over an extensive area on the radial half of the forearm and back of the hand. Stimulation with cotton-wool, the prick of a pin, the application of all forms of heat and cold, were unappreciated, and the two points of the compasses could not be discriminated, even when separated to the furthest extent possible. But if this part was touched with the point of a pencil, the head of a pin, or even with the ball of the finger, the stimulus was at once appreciated and the point of application localized with remarkable accuracy" (p. 102). "When the hairs were pulled, the elevation of the skin produced no effect on the consciousness. Pressure, which previously caused a sensation, was no longer appreciated when applied to the skin lifted from the subcutaneous structures to form a ridge. All sense of form or size was lost" (p. 103).

For a long time past neurologists have maintained the view that in speaking of the perception of pressure a distinction must be drawn between light pressure or touch and strong pressure or, as Strümpell more appropriately calls it, deep pressure. The perception of light pressure, of form and of size, is due to the skin, thanks to the sensibility of the touch-points and their highly developed discriminating and localizing power. The corresponding terminal organs are ring-like arrangements of non-medullated nerve-fibers encircling the hair follicles and, in the hairless parts of the skin, the corpuscles of Meissner.

The perception of deep pressure is much less accessible to investigation, because, under normal conditions, it is hidden by the superior sensibility of the skin. But it is known from clinical cases, particularly of syringomyelia, that the sensibility of the skin may be impaired or even lost, while the perception of deep pressure is apparently unaltered. So far as I am aware a minute examination of the state of sensibility in such cases has never been made. Undoubtedly a certain amount of localization remains and there is no ataxia in executing spontaneous movements, a disturbance never wanting when deep sensibility is lost. As to the terminal organs that are responsible for this kind of sensibility, Sherrington has rendered it very probable that they are to be looked for in the so-called "muscle-spindles." According to him, from one-third to one-half of the medullated fibers of the muscular nerve trunks consist of small-sized fibers connecting the spindles with the spinal ganglia.[7] There are, besides, terminal organs called corpuscles of Pacini and Golgi-Mazzoni to be found in the fibrous membranes, in tendons and joints. Head's experiment may be regarded as a crucial test, establishing the correctness of the above views.

A fact which puzzled Dr. Head very much he describes in the following way: "Over the radial half of the dorsum of the wrist a triangular area of skin became entirely insensitive to prick in consequence of the operation. But this same area remained sensitive to touches with cotton-wool and also, in a limited degree, to warmth. The area was capable of appreciating temperatures between 36 and 45° C. It was, however, entirely insensitive to temperatures of 50° C. and above."

If this description is to be taken literally it is difficult to understand, and, I think, very improbable. I venture to suggest the following interpretation: Temperatures of 50° were felt neither hot nor burning, but simply warm, just like the lower temperatures. If my conjecture is right, the observation can be easily explained by certain peculiarities of the temperature-sensations familiar to physiologists.

I have already spoken of the so-called paradoxical sensation of cold brought about by irritating the cold-spots with temperatures of 45° and higher ones. If the temperature of the normal skin is slowly raised over the physiologic zero-point, first the warm spots alone are irritated and the sensations lukewarm or warm evoked, according to the intensity of the stimulus. When the temperature reaches 45° the sensation changes in a peculiar way owing to the fact that the cold-spots join in the irritation, mingling their specific sensation with the warm one. Alrutz has proposed to reserve the term "hot" exclusively for this combination, and I gladly accept his suggestion. If the temperature is raised still higher pain is evoked, and the sensation assumes a burning character.

Now, if some part of the skin has lost the sensations of cold and pain, it is to be expected that all temperatures above the physiologic zero-point will be felt simply as warm, and that the sensations hot and burning will be absent. The possibility remains that the higher temperatures will not be felt at all, since it is a well-known fact that temperature-spots tire very quickly.

Another curious observation was made by Dr. Head during a certain period of recovery. From about the fiftieth day after the operation, sensibility of the skin slowly began to return, the sensation of prick appearing first, soon being followed by temperature sensations, but a year elapsed before light touch could again be felt. The temperature sensations were at first very imperfect. To irritate the cold-spots, which reappeared in small number, rather low temperatures were needed and conversely relatively high temperatures for the warm-spots. But whenever the spots reacted the sensations were strong and widespread, their localization indefinite and often erroneous. Similar phenomena could be observed when painful stimuli were applied.

I quite agree with Dr. Head in attributing to these observations a considerable importance, but I can not see them in the same light as he sees them. He thinks that these imperfect sensations of cold, warmth and pain are brought about by a special system of nerves, which he calls "protopathic." These nerves regenerate, according to him, more quickly than the "epicritic" ones, their threshold value is high, their sensations strong and varying little in intensity, the localization very indefinite, etc.

I may be now allowed to recall what I have said regarding the perception of intensity and locality of a stimulus. I pointed out that in producing these perceptions certain qualities of the central nervous system, such as summation, irradiation and others, play an important rôle. If a cutaneous nerve is severed, the atrophy of its distal end, of its terminal organs and probably of the skin is not the sole effect, but there occur at the same time marked changes in the corresponding spinal ganglia and their posterior roots. In a very elaborate research George Koester, of Leipzig, has shown[8] that the cells of the ganglia first swell and then shrink and that they remain for months in an altered condition. Similar changes take place in the posterior roots. According to H. K. Anderson,[9] section of the sciatica nerve in young animals checks the development of the corresponding ganglia and posterior roots and of the cells in Clarke's column of the same side.

---

[7] Jour. of Physiol., 17, 211, 1895.

[8] Koester, Gg.: Zur Physiologie der Spinalganglien, Leipzig, 1904.

These observations furnish ample proof that at the time of incipient recovery the central connections of the cut nerve are not in normal condition, which makes it probable that their function also is altered. If we assume, for instance, that through the degeneration process the connections of neurons are loosened, it seems quite likely that after the operation stronger stimuli are needed to evoke sensations than under normal conditions, and that the irritation once established is little changeable as regards intensity and irradiation, which means that summation and localization are very imperfect. The assumption is the more probable since it is known that certain drugs act in a similar way. I believe, therefore, that the many interesting points brought forward by Dr. Head can be accounted for by reference to certain well-established physiologic and pharmacologic data. It seems, therefore, at least for the present, not necessary to introduce a hypothesis to which existing physiologic and psychologic data do not lend support.

I am quite aware that the explanation that I propose, like his, is more or less a hypothetical one. Still it has the advantage, as I believe, of being consistent with all the observations as yet known. Of course, every hypothesis is by itself transient and has to be changed as experience grows. That is the reason why I have wished to bring the matter before you, hoping that your experience will show me how far my conclusions are right and where I have missed the point. I am quite convinced that physiology alone, unaided by clinical observation, would be very slow in unraveling the mysterious functions of the nervous system.

DISCUSSION.

Dr. L. F. Barker, Baltimore, said that the Section was to be congratulated on having had the opportunity of hearing Professor von Frey give the results of his investigations. In 1895 it was his privilege to meet him for the first time and to have him demonstrate the method for distinguishing these four cutaneous senses, touch, pain, cold and warmth. It so happened that Dr. Barker had in his arm an area of elective anesthesia, due apparently to a cervical rib. In this area he felt pain sensations, but no cold, no warmth, and no touch. It interested him especially because he had an opportunity to study pure pain sensations unmixed with any other. At Professor von Frey's suggestion he studied this area and the adjacent skin for some six months under his direction. It was illuminating to see how his delicate methods permit the demonstration of the various sense points. The fact that he experienced pain sensations free from the other sensations in the area mentioned speaks strongly in favor of von Frey's view of independent pain nerves. The pain points are so close together in the normal skin, and are so difficult to stimulate without stimulating sensory points of other modalities, especially touch points, that many have found difficulty in convincing themselves of the accuracy of von Frey's observations. After becoming acquainted with pure pain sense it was easily possible for him to localize both touch points and pain points, and to distinguish them sharply from one another in normal skin. Of the many names connected with the physiology of cutaneous sense those of E. H. Weber, M. Blix, and Max von Frey are the most important.

Dr. S. J. Meltzer, New York City, said that there was no pain from heat; he could not say as to cold. His observations were made under local anesthesia. In one case in which magnesium sulphate was used, an operation was performed and the patient did not know he had suffered any pain. He had also had experience in the use of cocain. When this is used the sense of touch is present although the sense of pain may be absent.

Dr. S. I. Franz, Waverley, Mass., said he would like to ask Professor von Frey to explain from his point of view the results of the temperature tests made by Head and Sherren. Most of Head's subjects showed a loss of ability to appreciate medium temperatures, but a retention of sensation of the extremes, but Head also describes at least one case in which the extremes were not felt although the medium temperatures were properly appreciated. The first of these conditions may be explained as due to differences in threshold values, but when coupled with the second it suggests very strongly the probability of two different sensory mechanisms, one for moderate and one for the extreme temperatures—in addition, perhaps, to the "heat" and "cold" end organs and conducting nerves, which Professor von Frey has so ably demonstrated.

Prof. Max von Frey said he agreed entirely with Professor Barker in the view that different kinds of painful sensations exist. They could all realize that from cutting they suffered a different sensation from that resulting from strain of a joint. Pain may arise in nearly all of the tissues, while cold, warmth and touch are limited to the skin and mucous membranes. He called attention to the important work of Professor Tullenberg, who had shown that by high temperatures two heat sensations are produced, one a superficial and the other a deep one. Of course this had nothing to do with the assumption of Dr. Head, who assumes that the skin is supplied with two sets of nerves. Professor von Frey thought it important to investigate the different effects of poisons on the sensations; of cocain on the eye, for instance. The eye is very good for the carrying on of certain experiments. In using cocain he came to the conclusion that there was a difference in the lapse of time in the disappearance of the sensations of cold, warmth and pain. He was unable to make very extensive investigations. As to the remarks of Dr. Franz he thought he had shown that the differences which Dr. Head has observed are in the main due to differences in the temperature. He had to apply higher temperatures usually. Of course they would have to wait for a final paper by Dr. Head, but it seemed unnecessary to hold to the conclusion that there are two sets of nerves.

There was another experiment which was very startling in its results when done for the first time. It consists of putting a part of the finger or hand into mercury, which of course puts it under a high pressure, and this is not felt. Why is this possible? A very light touch will arouse the sensation of touch, while this will not. Professor von Frey found this to be due to a peculiarity of the touch nerves.

A SUMMARY OF THE THERAPEUTIC FIELD FOR THE PAST YEAR.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON PHARMACOLOGY AND THERAPEUTICS AT THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, BOSTON, JUNE 5-8, 1906.

THOMAS F. REILLY, M.D.
NEW YORK CITY.

Custom and the by-laws of the Association have ordained that your chairman shall outline the progress and advance in pharmacology and therapeutics during the year. To mention all of the advances in therapeutics in the past year would require a résumé of the progress made in the cure of disease in all the departments of medicine. The scope of this Section really embraces the whole art of curing disease and everything of a therapeutic nature is an open field for our discussion. I shall take up only those therapeutic measures that directly interest the general practitioner.

---

[9] Jour. of Physiol., 28, 499, 1902.

GENERAL REVIEW.

The number of useful remedies introduced during the past year has been very few. It is true that the usual horde of organics and synthetics made in Germany have come, though with somewhat abated vigor, but thus far few have been of any signal service. Doubtless a potent cause of the failure of the new agents to attract attention is due to the fact that experimenters, reputable and otherwise, are now more chary in extolling the imaginary advantages of a new agent than they were before the crusade of the past year.

Better appliances and more experience are responsible for the increasing use of ethyl chlorid as an introductory anesthesia, preparatory to administering ether. For this purpose it is rapidly replacing the more cumbrous nitrous acid and is apparently quite as safe. The great claims set forth as to the value of scopolamin-morphin anesthesia have, in a measure, fallen to the ground. At one time proposed as a general anesthetic and now used as a preparative sedative to ether anesthesia, it is but slightly superior to morphin and atropin. For many years morphin and atropin have been used for the purpose of quieting patients before anesthesia, and for this purpose scopolamin and morphin have scarcely any other advantages. The lack of excitation is more than counterbalanced by the after depression. Chemically, it is the same as atropin and the Phamacopeia regards it as an equivalent. Like the Greeks, we are always running after the old gods with the new names.

The treatment of syphilis by hypodermic injections of soluble salts of mercury has, during the past year, received a great impetus, by reason of the almost unanimous advocacy of this measure by the eminent syphilographers who have written on the subject. It is safe to say that the treatment of syphilis by inunctions will soon be a thing of the past. In Germany the intravenous use of some of the preparations of digitalis has achieved decided recognition; in this country nothing has been done in this line as yet.

No new organic silver salt of any consequence has been launched within the past year. Sober second thought is gradually convincing us how seldom it is possible to "shoot" the virulent germs and the number of successful results reported from the use of organic antiseptics has materially diminished.

A few new cocain substitutes are now before the profession awaiting trial. Personal observation leads me to believe that their seeming advantages are more than counterbalanced by other disadvantages.

Little has been heard during the year of the use of large doses of creosote and its derivatives in the treatment of pneumonia. Doubtless, it is still employed to a large extent for this purpose, but except for its effect on an accompanying bronchitis, the impression is gaining ground that it is not of any distinct service. From the Southwest, where, apparently, pneumonias are of a milder type than ours, comes a second champion who lauds massive doses of quinin and chlorid of iron as a specific in the treatment of this disease. It may be said to be still on trial, but certainly we in the East can not get the good results that its sponsor says he achieves in the Southwest.

In the large metropolitan hospitals there is a feeling of therapeutic nihilism as to the medicinal treatment of pneumonia, and in the vast majority of cases the treatment is expectant in character. It is safe to say that strychnin is the only agent used with any constancy. The mortality rate of from 20 to 40 per cent. certainly should be modified by judicious medication. The tendency to secure medicinal agents from animals rather than from the plant kingdom, has increased during the past year. The use of Moebius serum of thyroidectomized sheep has been established as a measure of practical value in the treatment of exophthalmic goiter. The serum of Beebe and Rogers, although differing very much from that of Moebius, promises well. The Italians have been very active in this line of work and many favorable observations have been made by them in the treatment of leukemia and anemia and other blood diseases with various sera.

There has been little added to our knowledge of the therapeutic value of the suprarenal glands; on the other hand from several sources a note of warning has come as to the use of subcutaneous injections of its various preparations. In not a few instances sloughing has followed its use. The continued use of the active principle of this gland in animals has unquestionably induced degeneration of the walls of the arteries. This is a point to be kept in mind when this agent is frequently employed in human beings.

The number of the diseases beneficially affected by the Roentgen ray therapy has not received any material increase; on the other hand the field of usefulness formerly claimed for it has been much restricted.

During the year the tendency to use large doses of antitoxin in diphtheria has become more manifest. A most important advance in this connection is the confirmation of the value of antitoxin in postdiphtheritic paralysis, even though the patient has already received antitoxin. The intravenous use of this agent does not seem to have found favor, although there are cases in which it is worthy of trial. The diphtheria antitoxin has been used for well nigh all disorders from acute articular rheumatism to cerebrospinal fever and competent observers have reported good results from its use in most of them. Whatever good effects that may have followed its use were due to an inherent immunity possessed by the horse before the diphtheria toxin was administered. Later observations do not warrant any hope from its use in cerebrospinal fever. As a prophylactic agent antitetanic serum may be regarded as a specific. In up-to-date hospitals its use in all cases of punctured wounds has become a routine practice. This is especially the case with blank cartridge wounds, and the number of cases of tetanus have markedly diminished. When the disease has begun the injections of the serum into the motor nerves, spinal canal and brain, offer the only hope. For a long time the use of the antistreptococcus has been regarded in the light of an experiment. There is reason to believe that the use of polyvalent sera has been followed by marked results. The field of usefulness is much like that of antitetanic serum, in that it acts better as a prophylactic in suspicious cases than as a curative agent after the establishment of the serum disease.

No confirmation of Behring's antitubercle sera has been reported. Hoffa, of Berlin, in the *Revue de Thérapeutique* speaks very encouragingly of the use of Marmorek's antitubercular serum in cases of bone and joint tuberculosis. He reports a series of thirty cases wherein the use *per rectum* of large doses of this serum has been followed by unmistakably good results.

On many occasions the word has gone forth from this Section that a more systematic study of our native plants would enormously enrich our medical armamentarium. If one-half of the energy that is daily put forth to discover some new coal tar product were employed to test our native plants and to extract their active principles, I am sure far more permanent results would be obtained. Why should there not be other plants growing about us, that will do for other organs what digitalis does for the heart and what quinin does for malaria? Coal tar derivatives have never cured disease. In every case their effects are but temporary. The reason of this present skepticism of the profession toward our native materia medica, is doubtless due, in a measure, to the senseless claims made by earlier inexperienced and too often uneducated physicians and laymen, claims which were found to be preposterous. If it were found that the agent did not benefit the disease as it was claimed to do, it rapidly fell into oblivion. This is not the method of the ultrascientific staff pushing a new coal tar derivative. They keep on trying it for everything and finally it may become a well recognized agent, useful for an entirely different affection from that which its originators intended.

THE PHARMACOPEIA.

The past year has witnessed the launching of a number of pharmacopeias. Those of European countries, as well as our own, have in the main, adopted the principles laid down in 1902 by the Brussels Conference. This has resulted in a uniform standard of strength and character for most medicinal agents throughout the civilized world. In this country hitherto, the appearance of a new edition of the Pharmacopeia has excited little notice on the part of the profession. A few college professors felt obliged to keep abreast of its teachings, but the general body of the profession had come to view it as being essentially a druggist's book. This year the condition is vastly different. The few changes that have been made in the strength of some of the well-known drugs have attracted the attention of the rank and file of the profession and there is a constant demand for instruction on the rules, changes and suggestions contained in the new work. Probably the most far-reaching result of the new edition is the establishment of the so-called purity rubric, whereby all articles which bear such a standard are restricted in their absolute purity without necessarily criticising minutely as to what the fraction of a per cent. claims to be. Such rubric gives all of the courts of our country a standard which they have long plead for to base their findings on and lends more protection to the public than a casual observer can realize. It is now believed that more frequent revisions of the pharmacopeia are necessary and it seems to me that the time has come when the American Medical Association should take a hand in this work. With our Council on Pharmacy and Chemistry, with a laboratory force, and with a journal as a mouthpiece of the entire profession, we are better equipped for the work of revision than any body which could possibly be selected as the Pharmacopeial Conventions have been in the past. Far from having any intention to impugn the work of the committee on revision, than which a better never existed, it is my belief that if the medical staff of the committee were selected by this Association and the pharmaceutical and chemical staffs by the national chemical and pharmaceutical associations, the revision would more nearly be an expression of current medical usage. As it is many agents have been retained that are not in general use, while others much used have been omitted. A national organization is eminently fitted to find out such facts and to give the book a national character.

THE CAMPAIGN AGAINST NOSTRUMS.

Of all advances in therapeutics during the year, none is more noteworthy, none will be more lasting to the whole art of therapeutics, than the war against nostrums and semi-secret preparations. It is safe to say that the campaign which has been waged by The Journal of this Association for the past two years and by various lay periodicals during the past year, has made thousands of physicians turn to the writing of pharmacopeial prescriptions rather than prescribing some confessedly secret prescription or proprietary, which often amounts to the same thing. This is distinctly a therapeutic advance and as it is potential for further growth it is all the more commendable. Many of the waves of moral upheaval which have characterized the past year in the different spheres, will doubtless recede as they have done before, but with this matter there can be no backsliding. The establishing of the Council on Pharmacy and Chemistry marks a pillar which as a permanent institution will always hold a beacon light to show the difference between the true and the false. Next to The Journal, it is the most valuable asset of the organization, and it is hoped that its work will be brought to the door of every practitioner of this country free of cost, whether he be a member of the organization or not.

WHY PROPRIETARIES ARE POPULAR.

It is not my intention to discuss the ethical and nonethical proprietaries; others have done that more exhaustively than we have time to do here. It seems to me that the chief reason for the use of the proprietaries is not that they contain any wonderful medicinal agent or combination of agents, but that they do present disagreeable tasting medicines of more or less value in a palatable form. We may say that it is a small matter, that the relief of distress and the cure of disease are our chief objects, but the present generation is a generation of sensitive stomachs and sensitive nervous systems, and the small things such as a disagreeable potion are to them a major affair and in many instances cause more discomfort than the disease, hence the vogue of homeopathy among the well-to-do. For instance, scarcely any one really believes that the modern organic iron preparations are intrinsically better than the old pharmacopeial inorganic salts, but it is the general belief founded on experience that, as furnished by the manufacturers, they do not disturb the stomach and are not repellent to the taste. I might mention many other similar instances. This brings the matter squarely up to the medical schools as far as the next classes of graduates are concerned. For those in practice it is no new advice to tell them to study pleasant combinations. By asking the advice of competent druggists many improvements in the routine prescriptions can be suggested. This must be a matter of individual education.

In some instances it seems that it might be a good plan to fill in the active ingredients of the prescription, quantity and dosage, and then to state that the druggist can use his own skill in making it palatable by the addition of flavors, etc. Such additions should then be incorporated in the prescription. In this way the druggist will take some pride in filling prescriptions and the more skillful he becomes the more patronage he will receive and thus he will be compensated.

THE DRUGGIST AND THE PHYSICIAN.

Another plan for educating the profession individually is that pursued by the druggists' association in several parts of the country. Circulars explaining the palatable prescriptions of the *Pharmacopeia* and of the National Formulary are sent monthly to all physicians in the neighborhood. The profession has generally been skeptical as to the ability of the retail druggist to make elegant and palatable preparations, and this notion has been fostered by the various proprietary agents. This was all too true of the slovenly druggist of a decade ago. To overcome this prejudice some of these up-to-date druggist associations before mentioned have followed the example of the detail men of the proprietary firms and are sending neighboring physicians small samples of the pharmacopeial articles as dispensed by them. These are in every instance the equal in quality, taste and appearance of any similar proprietary. Many physicians may not relish such instruction offered by the pharmacist. but it is a thousand per cent. superior to that dispensed by the average detail man. In a number of cities joint meetings of the local druggists and physicians have taken place and as a result a better feeling has been engendered.

This Section forms a link, as it were, between the druggist and the physician, and we hope in the future that closer relations may be maintained with the national pharmaceutical society. Plato's dictum that great questions are only to be decided by compromise holds good for this matter of the proprietaries. Some features of the proprietary trade must remain; others must go. Out of the present clash of interests and theories certain well-defined principles will be evolved that will form a basis for a newer science of therapeutics.

HEALTH INSPECTION AS APPLIED TO THE INDIVIDUAL.*

LOUIS FAUGERES BISHOP, A.M., M.D.
Physician to the Lincoln Hospital.
NEW YORK.

The care of the health, when it comes to a discussion of its restoration when it has been lost, is a very old topic. Health inspection, as a wholesale proposition, as applied to communities, states and countries marks in its development perhaps the greatest advance in the application of science to human welfare. As applied to the individual, it still lags far behind what it ought to be.

Hundreds of lives are lost every year, and thousands of days of disability incurred because it is not the custom for the health of the individual to be the subject of inspection in such a manner as to detect and remedy disease in its beginning.

The life insurance examination which, of course, is only applied to relatively few individuals, reveals a surprisingly large amount of unsuspected disease.

Every individual should be thoroughly inspected from time to time by a physician applying the resources of a complete physical examination, with chemical and microscopic observation of all obtainable secretions, in order to ascertain the standard of health of the individual.

No one would think of running a complicated machine without an annual inspection and overhauling of those slight defects which, if neglected, lead to a serious breakdown.

Each generation as it advances through decades considers itself an exception to the one that preceded. and no one accepts the penalty of advancing age until it is thrust on him. The laboratory would inevitably reveal the necessity for attention to diet years before incurable physical penalties had been uncured.

Such an examination to be of value must be very technical in its nature.

Patients naturally seek the physician for disordered conditions that are sufficiently obvious to attract their attention.

The observations necessary to determine the standard of health of the individual in the absence of evident disease are so technical, consume so much time, and require so much manual dexterity, that the examinations themselves must usually be made by young physicians whose attention can be devoted chiefly to these things. But the young physician is unable to judge of the relative importance of the very technical details which he is specially capable of discovering. For this reason, the general practitioner, or as he has come to be called, in these days, the private practitioner, should have his practice so organized as to obtain the assistance of younger men who have fresh skill and enthusiasm with regard to the technicalities of physiologic observation. Comparatively few men have reached the point of such an organization for themselves alone. Some of us have brought this about by the establishment of a coöperative clinical laboratory, where the younger men who are fresh in all the technicalities of chemical and microscopic research do the work of older men, who are in actual practice.

Such a laboratory must be under the direction, more particularly of one man or a committee, but so long as it is purely coöperative in spirit, in that everything is done for the interest of those who come into the arrangement, and so long as the laboratory remains a place where actual practitioners meet to discuss technicalities with the younger men, and the significance of things with their fellows. it will tend to make clinical pathology a practical matter to actual practitioners. It is by means of such an organization that we may arrange our clientéle so that the continuous observation of each individual, while in apparent health may lead to the early detection of disease. The number of people who are willing to submit to this system is, unfortunately, comparatively small, but when its advantages are once clearly understood the number ought to be larger.

The individual must be trained to employ his physician to watch his physiologic processes in the same way as the public has come to expect the medical profession to watch over the health of the community.

Every person should possess a record of his physiologic standards and peculiarities for reference in case of suspected disease.

The united profession can work for the wholesale care of the people, while it is very hard for an individual physician to approach an individual citizen with a proposition for continuous care. This must be brought about by gradual education.

DISCUSSION.

Dr. S. A. Knopf, New York, said that Dr. Bishop had outlined the ideal future life of the average American citizen. He will have his own private family physician; if he can afford to pay for it, all right; if not, the municipality will pay for it. Dr. Knopf commended Dr. Bishop's ideas about the necessity of periodic examination of the average individual, particularly those predisposed to disease. Dr. Knopf said that in the tuberculosis crusade he has emphasized this point particularly in families predisposed to tuberculosis. If we wish to combat tuberculosis as a family disease, in the schools.

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-seventh Annual Session, June. 1906

and in the educational institutions, it is absolutely necessary, he declared, that we should have an entrance examination not only intellectual, but physical, that children should be reexamined at least every six months, or yearly. He said that these suggestions are a little utopian, nevertheless they are ideals; without enthusiasm we can not attain anything.

Dr. M. Friedrich, Cleveland, said that one can not even get the examination of the school teacher, a most necessary thing. He can not force an examination, even, of a man who drives a milk wagon, which is absolutely essential. No man who has tuberculosis ought to handle milk. He can not get the examination of the bakers. The man who handles bread ought to be examined. It will take years and years to establish examination of individuals; for as soon as one attempts to examine an individual he will say: "You are encroaching on my personal liberties," and that is just where the shoe pinches.

Dr. Seneca Egbert, Philadelphia, said that while he agrees with Dr. Knopf that Dr. Bishop's proposition is rather utopian at present, he would like to suggest that there are places in this country where it is, in a measure, put in force; namely, in many of our colleges. While the physiologic examinations there are not complete and are largely anthropometrical, they do good by giving the authorities in the colleges a knowledge of each individual entering them whether as freshman or in a later year, and they give the students who enter these colleges a better knowledge of themselves and stimulate their fear, their ambition or whatever it may be, so that they get to work in the gymnasium and improve their condition, as is manifest within the first six months after entering and being examined. In the four years the improvement is remarkable and Dr. Egbert thinks one could say that the average condition of the men who go out from the colleges where such preliminary examination and anthropometrical work is carried on, is far better at the end of the four-year course than that of the men who go out from colleges where such examinations are not made. It also seems to him that here we have the kernel of the right beginning of the movement—that the men and the women who go out from such colleges are the very people who should carry this idea out among the laity and who may be powerful coadjutors of the physician who wishes to help this along. It is true that the idea is utopian at the present time and that it will take a long time before we have everybody examined; but when we appreciate that we have to-day three or four thousand people in our colleges who might be good, stanch advocates of such ideas in the future, and when we get down to the fact that sooner or later we must teach in our normal schools these very things and there develop these very ideas, we have the way made clear for a good beginning. We then will begin to be able to have the school teachers examined, after them the pupils, and so in time, he said, a comparatively large portion of the population will come practically within the scope of Dr. Bishop's suggestions.

Dr. Louis Faugeres Bishop, New York, declared that he is a great advocate of keeping young men who are beginning the practice of medicine at all kinds of pathologic and physiologic examinations, and said that these young men are glad to do the work in chemical pathology arising in the practice of old practitioners. He said that only by coöperation with such workers would it be possible to carry out his idea of health inspection.

Function of Pancreas in Metabolism.—Ugo Lombroso has recently published a report of considerable experimental work on this subject. He found that the disturbances caused in dogs by ablation of the pancreas were not modified by introduction of pancreatic juice into the duodenum under conditions closely approximating the normal. This demonstrates, he thinks, that the disturbances can not be the result merely of the lack of the pancreatic juice, but that they must be due to a missing internal secretion of the pancreas. This assumption is favored by the singular persistence of the islands of Langerhans after ligature of the pancreatic duct in rabbits. This persistence suggests that these islands participate in some internal secretion independent of the secretion of pancreatic juice. Lombroso's work is reviewed in the *Gazzetta degli Ospedali*, No. 68, 1906.

SOME TRUTHS ABOUT SLEEP.*

NORMAN BRIDGE, M.D.
LOS ANGELES, CAL.

In the popular mind there must be some mistakes about sleep, so variant and dissimilar are the views as to the need of sleep, the effects of it, and of the lack of it.

One man is sure that for health and strength he needs only four or five hours of sleep out of each day of twenty-four hours, and he quotes numerous people above childhood who have like views and experiences. Another must have eight or nine hours and cannot do with less, and, as all men tend to measure others by the yardstick that fits themselves, he is sure to believe that no one should have less than one-third of his existence spent in sleep.

The medical profession freely teaches this latter view and insists that children especially must have an abundance of sleep or be in peril of nervous and mental bankruptcy. We are told that infants should sleep a large part of the time for safety from calamity to their brains, yet there are instances of infants and small children who have for many months together slept less than four hours in the twenty-four and come out of the experience with vigorous minds and bodies.

INSOMNIA: A WRONG THEORY.

Great numbers of people in our modern life of high nervous tension are victims of insomnia, more now than ever before, and the number is apparently increasing rather rapidly in certain communities. Drugs to produce sleep were never in such demand, were never used so freely, both as a temporary expedient and as a daily habit, as now; and they are sold in vast quantities all over the nervous world, and used according to the whim of the sleepless, more often without than with the advice of physicians. Insomnia is therefore a favorite harvest field of the exploiter of "patent" nostrums, for he well knows that, driven to desperation by sleeplessness, its victim is ready to do anything that promises relief; and if sleep comes as an effect of a drug he is ready to forgive other and perhaps resulting ills, that may in the end be worse than the insomnia.

Possibly some of the sleeping potions may do good by helping to sleep without inflicting any incidental harm to the system, but the evidence is strong and accumulating that most, if not all, of the soporific drugs do harm in some way, especially the coal-tar products and all those that work their effects by obtunding the sensibilities of the nervous system. While their use may be justified by an occasional exigency, they are in the main mischievous because, if for no other reason, they undertake a function and do a thing for the body that good hygiene and a better course of living, as a rule, should make unnecessary.

The testimony of patients with this affliction certainly seems, on the face of it, to confirm their theory of the seriousness of insomnia, for they find that a night without sleep, even if they are in bed and bodily resting, unfits them for the duties of the coming day, and that after a good night, they are fresh and strong. And these data are correct; after a wakeful night these patients are unnerved for the day, and after a night of good sleep they are fit and cheerful. Whether their theory is correct that lack of sleep alone does the mischief is another matter, and there is reason to doubt this conclusion and to suspect, if not to know, that the insomnia is only one of several factors in the problem; one of several co-results of a common and another cause and not itself the sole cause of all the harm.

---

* Read before the Association of American Physicians, May 16, 1906.

There can be no question that the victims believe implicitly in the current theory. They easily come to dread a sleepless night; they look forward to such a possibility with nervous apprehension, if not horror, which makes them less likely to sleep; in the throes of wakefulness when they have gone to bed for the purpose of sleeping they become so annoyed as to make sleep hard or impossible to court, and so they lie awake tossing in restlessness and chagrin till morning; and afterwards they look back on the experience with a sense of gloom.

INSOMNIPHOBIA.

It is not unnatural that they should attribute all their bad symptoms to the lack of sleep, for that is the easiest generalization; but it is only half true, if true at all. It is vastly important in this study to keep the horse in front of the cart, for the tendency is great to reverse them. The true story is that the horrors of insomnia are slightly due to want of sleep—very much due to insomniphobia, with which, in some degree, nearly every such patient permits himself unnecessarily and foolishly to become afflicted. His experience is analogous to that of the patient with phthisis who has night sweats. This latter believes, till he is taught otherwise and better, that his bad day is due to the night-sweat preceding it. This is a natural but a most unscientific inference for the patient to make. Really, the bad day and the sweat are co-results of another and a different influence; they are not cause and effect. When the patient learns this truth and that the sweat is not harmful in itself, but a possible benefit by the expulsion of poison, he discovers that it is only a trifling inconvenience, not a calamity, and he bears it with equanimity, if not with pleasure.

The victim of insomnia is equally wrong and equally unfortunate in his reasoning about his case. He honestly believes that loss of the sleep which he thinks his due, is fraught with the certainty of great injury; he laments his infirmity and fears he may become insane, and becomes nearly so by his worry, when if he could and would stop his fretting, he would find that he was hardly hurt at all. The very attitude of his mind when he goes to bed tends to keep him awake, for he is in a state of mental expectancy of insomnia, and the longer slumber is delayed the more demoralized he becomes, the more exalted is his irritation, and the less likely is he to fall asleep. What is worse, he is very unhappy about it and this mood tends still more strongly against slumber.

If he can go to bed and sincerely resolve that he does not wish to sleep, but would rather keep awake all night and perhaps read a book or otherwise try to drive off slumber; if he can bring his mind to this mood, which is one of pleasure at being awake—then he will fall asleep before he knows it and probably so remain the night through. The chief thing is the mood of pleasure, or lacking that, stoical indifference as to whether sleep comes or not; it makes the terror impossible and brings enough sleep in nearly every case—not eight hours it may be, but enough.

REST FOR THE BODY.

There is another truth about this subject that is even more fundamental, and one that is substantially never mentioned by students of it. This is that our theory is wrong that we go to bed and stay there eight or ten hours a day for the chief purpose of sleeping. Sleep, go to sleep, get sleep, sleep is the great restorer, blessed sleep—these are the cries that always ring in our ears, and that have probably in some form rung in the ears of all the recent generations as indicating the drift of thought about sleep. But it is a narrow and a one-sided view. Of course sleep rests the tired brain and lets its cells recuperate from the strain of labor that lowers them, but what of the weal of the tired body whose tissues have been lowered by the work of the day? This consideration has been almost wholly neglected in our scheme of reasoning and the poor body has had to get what benefit it might as an incident of the sleep. On the contrary, we should go to bed to rest the tired body and let sleep come as an incident; rest of the body should be the chief aim; go to bed for that purpose and the sleep will mostly take care of itself. Man can, by his volition, send his body to bed as readily as he can chop his wood, and so his body rests; but sleep comes as a sequence of the conditions of his body, i. e., fatigue, horizontal posture, quietness, silence and darkness to shut out impressions and to incline the brain against thinking; it does not come and never can come by an act of the will, as one rises and walks. The brain puts itself to sleep, so to say, involuntarily as the conditions entice.

The body should probably, with an active life, rest about one-third of the time, and it is not necessary that the brain should be unconscious in sleep all this while. Perhaps no one sleeps too much, but we have had surely an extreme estimate of the amount of sleep which it is indispensable that a rested body should have. This is a most practical truth; and every insomniac who gets himself down to or up to this mental basis begins at once to benefit from it, and he finds that lying awake an hour or two of a night, or before rising in the morning, is not only not harmful, but is not specially unpleasant. Then he is surprised to find his terror gone: he ceases to be an insomniphobiac and becomes a happy philosopher.

CULTIVATION OF A PROPER MENTAL ATTITUDE.

But this mental basis is one of the hardest things in all the experiences of life for the distraught poor sleepers to reach. It is hard for them to change their philosophy of sleep and their habits about it. They have unconsciously and unwittingly come to regard the act of lying in bed awake in the night as a punishment, if not a sin. They are chagrined if they do not drop off to sleep promptly on going to bed; and if they waken before daylight they fret till rising time, or they get up before their rest is over because they are awake. This fuming tendency of the mind is a most interesting study. It is quite as likely to reveal itself about a trifle as about the momentous things of life. A man will be extremely annoyed and impatient because you keep him taking a pill three times a day for weeks, although the pill is sugar-coated, is swallowed easily and produces not a symptom of which the patient is conscious. If it were a sugar-coated bread pill and he did not know this, he would grieve about it as freely. And we are all witnesses of countless lamentations of people because of trifling discharges from their throats and noses of harmless mucus each day. We know and they know that no pain or discomfort comes of it, yet they are in daily terror of the awful consequences they suppose to attend this trifling thing labeled catarrh.

It is hard to unlearn the lessons of a lifetime which are reinforced by beliefs that are hereditary from a thousand generations of usage, and to see as agreeable the things that have always been considered disagreeable. The sleep problem illustrates this to a high degree. One of the hardest sides of this problem is the contention that much less than the classical eight hours of daily sleep will do. But there are many facts to prove this thesis. People who lie abed long hours reading, sleep correspondingly little, and they live as long and keep as well as the average. It is notorious that many eminent men of history have slept little, and I think hardly one who can be called an intellectual giant has been accustomed to a great amount of sleep.

A CHILD'S EXPERIENCE.

Nor is it necessary that children, even infants, should have as much sleep as we have supposed. Many years ago my eyes were opened by an experience with a wakeful baby. He slept only about three or four hours a day on an average for a year, as shown by the most accurate of records, this wakefulness being due apparently to some nervous predisposition. Quieting drugs were tried, but it was soon found that dangerously large doses would be required materially to increase his sleep; and so, fearing the drugs more than the insomnia, his treatment was confined to good nursing and good nutrition. *I fully expected that the child's brain would be permanently* harmed by this experience, but nothing of the sort happened. At the end of a year and a half he was sleeping better, and by the end of his second year he was getting as much sleep as the average child of his age, and he was well and vigorous and had a good mind. Then a strange thing happened. He began to sleep more than other children, and by his fifth or sixth year, when he began to go to school, he was sleeping about fourteen hours. By his tenth year he seemed to have paid back to Nature what had been lost and was sleeping like other children of his age. He was perfectly well in mind and body, active and mischievous, and was well abreast of his schoolmates in his studies. One such case is enough to demolish the theory that a child must, that all children must, sleep a great deal or be ruined.

It is a common experience for a man to put off his bedtime till a late hour because he thinks he can not sleep till then; or to walk or work so as to tire his body profoundly before going to bed, in order that he shall be sure to sleep; or to get up at an absurdly early hour in the morning because he has awakened and can not sleep any longer. In all these ways he is wrong, for in them all he follows the wrong theory that we should go to bed chiefly for sleep. We are foolishly terrified by lying in bed awake, in the dark and with nothing to do. We are as bad as children afraid of ghosts. It is an unreasonable and an unreasoning fear, and one that any sensible person should have no difficulty in putting aside if he will only stop to think about it.

The body must be well rested every day, and in the horizontal posture. The erect position that is maintained through nearly all the waking hours makes this indispensable. We are physically handicapped as compared with the four-footed beasts; we need more rest of body than they, and rest horizontal, and if we get enough rest of body we usually get enough sleep if we only let ourselves sleep and do not worry to prevent it. But we should, as far as possible, seek those physical conditions that physiologically encourage sleep while we are resting. That rest of body is more necessary than much sleep, and that insomnia is clearly provoked by an easily prevented mental mood, are no warrant for us to neglect any of the obvious aids to easy slumber.

CONQUERING THE NOISE NUISANCE.

Light keeps some people awake; usually more than need be because they worry about it and magnify it as an impediment. Most people can have their bed hours in the dark; they can either go to bed early enough to have eight hours dark, or they can darken their rooms. Many are kept awake by noises great and small; often needlessly kept awake by trifling sounds that would be wholly negligible save for their propensity to be nagged by them. The irritation grows by indulgence; every time they hear the sounds and regard them as annoying, the horror grows. If the noises are produced by people or by animals, and are therefore preventable, the offensiveness is usually greater; the sounds of wind and waves and rain, or even gentle thunder are less sleep-killing than the coughing or snoring of an innocent neighbor or the distant barking of a dog.

Most people can overcome very much of any morbid sensitiveness to sound if they understand these truths and will try. But few will try hard enough and be wise enough for this consummation; and so some remedy for the noises of creation is proper for such people, if a remedy can be found that is harmless. The measure, whatever it is, must be mostly subjective, the noises themselves can be controlled but little; they must be kept out; the sound waves must be prevented from entering the ears. Cotton stuffed into the ears does a little good, but some waves pass through it unless it is packed so firmly into the meati as to cause discomfort, which, of course, renders the scheme nugatory. A cloth or other dressing tied over the ears may keep out many noises, but here again the apparatus, in order to be efficient, must press so tightly as to frustrate its purpose by the discomfort it causes. The thing needed is an air-tight, non-vibrating stopper for the ears; one that will not itself make a disagreeable sensation by pressure or otherwise; one that is easily applied by the patient himself, and one that is harmless. Common paraffin seems to fill these conditions; it is easily used, is harmless and wonderfully efficient. A small mass of the substance is warmed in the mouth, chewed perhaps to soften it the more rapidly, and is then pressed firmly but gently into the ear. It adjusts itself instantly to the external meatus, hardens as it cools and remains an almost complete bar to the passage of sound waves, without producing a disagreeable sensation, indeed, with so little sensation of any sort that its presence is soon forgotten. It is applied at bed time and removed by the finger in the morning; or it may be worn during the day if it comforts the patient, but not all the day for fear of interfering with the normal drying of the external ear. It may be used in this way for a long time with no harm of any sort and with the great advantage that it makes the patient nearly, or quite, independent of the unavoidable noises of his environment. This device may render it unnecessary to go to the country to sleep in order to escape from the city noises; it may make it less necessary to keep the children still to avoid waking their elders, and it may help the sensitive children to finish their naps in spite of the inevitable noises of the day.

OTHER TROUBLES.

Many people are poor sleepers for want of sufficient clothing in bed; cold feet are especially apt to keep them awake. A good bed is needful, for it rests the body most and so helps towards sleep. The remedies for these defects are obvious, but often beyond reach. Overfeeding often causes insomnia, if it does not make the drowsiness of indigestion, causing heavy sleep in the early evening and miserable wakefulness afterward; and overstimulation, especially with tea and coffee, is often fatal to good sleep. These troubles are always correctable. A loaded large intestine often keeps a sensitive person awake for half the night, when a prompt evacuation by an enema, a glycerin suppository or a quick-acting saline, relieves the insomnia for the time completely Foul air to breathe is a frequent cause of wakefulness; for this the remedy is fresh air in great abundance; and people do not take cold in well ventilated bedrooms.

When people are up and about they rarely become sleepy because their brains are tired. They often thus are sleepy, but this is mainly due to fatigue of the body or to some disarrangement of the digestive organs. Sleep comes normally with a normal and unabused body that has been fatigued a little and then been put to rest, and it is helped by cessation of active thinking, by darkness, by stillness, by mental tranquillity and a happy spirit. These things are first to be secured if possible; then the sleep comes as a natural consequence and, with hardly an exception, in sufficient amount. The sleep is secondary, not primary; these other things are primary and of great importance.

We must not count the hours of our slumber for fear it is not enough; that would break the charm of the influence and spoil the game. We may keep a record if we like, and it may be useful for our amusement and to help to fix the exact amount of sleep (which now no man knows) that, in our social zone, is physiologic for the man, woman and child of the present century with their varying orders of enlightenment and manifold grades of work and play. But this question can never be settled by the one poor slave of insomnia or by a thousand of them, and the question can wait. It profits each such unfortunate to neglect the race interests for his own, and to put his mind, in the calmest sincerity, to the task of saving himself from his thraldom—and the task need not be hard nor its benefits uncertain.

THE TREATMENT OF THYROIDISM BY A SPECIFIC SERUM.[*]

JOHN ROGERS, M.D.
Surgeon Gouverneur Hospital, Assistant Surgeon St. Francis' Hospital.
NEW YORK.

As the atypical forms of exophthalmic goiter are common and often overlooked on account of the nomenclature, it would be more accurate and at the same time less confusing to designate the condition as hyperthyroidism or simply thyroidism. The cases can be classified somewhat in the order of frequency of their occurrence in the following groups:

1. Simple chronic exophthalmic goiter or thyroidism of moderate severity with all the symptoms which gave origin to the name.

2. Atypical thyroidism which includes many of the early cases and those with more or less irregular symptoms, such as absence of goiter or of exophthalmos or of both; or those which complain chiefly of gastrointestinal disturbance with pain.

3. The chronic toxic cases of thyroidism or severe forms of the disease with slight fever, which may be the terminal stage of the common atypical form, or show little or no exophthalmos or goiter from the outset.

4. The acute toxic thyroidism presenting a clinical picture which Dr. W. G. Thompson has aptly compared to that of malignant endocarditis. These patients show little or no exophthalmos and a small soft thyroid and suffer from fever which may be quite high.

5. The psychopathic or neuropathic cases of thyroidism, which are a comparatively rare but, from a therapeutic standpoint at least, an important group. They give symptoms which sooner or later indicate organic change in the central nervous system and are only relievable in the early stages of the disease.

SYMPTOMS OF THE DIFFERENT TYPES OF THYROIDISM.

The most characteristic symptoms are those dependent on the vasomotor and nervous disturbances. The cutaneous blushing and feeling of heat, the "nervousness," tremor and often insomnia and the tachycardia with a soft, weak pulse are quite constant in all cases.

The exophthalmos and goiter may each vary within such wide limits that they should be considered as much confirmatory as positive signs. The subjective feelings of general discomfort, weakness, throbbing of the heart, dyspnea and frequently abnormal thirst must be borne in mind, as they are generally the first to disappear in any given case if the serum therapy is to succeed, while the other symptoms usually improve very slowly.

The *atypical group* includes some of the incipient cases which show no goiter nor exophthalmos, but can be recognized by the vasomotor and nervous disturbances; and the cases with goiter of long standing which not infrequently develop marked thyroidism quite suddenly and have no exophthalmos; and, finally, the cases usually with no exophthalmos but some goiter, which at irregular intervals suffer from pain referred to the abdomen or thorax and evidently due to excessive fermentation of food. At these periods the pulse becomes very rapid, but otherwise the whole clinical picture is one of acute indigestion, and unless the goiter were noted in conjunction with the tachycardia the probable cause of the difficulty is easily overlooked.

The *chronic toxic* type of this disease presents no particular difficulties in diagnosis, except that I have seen it occur and give every evidence of ultimately proving fatal with a decreasing exophthalmos, goiter and pulse rate, the greatest danger seeming to lie in the exhausted and degenerated heart muscles. It is in these chronic cases that the bad secondary lesions of blood stasis and general anasarca dependent on the impaired cardiac action become so prominent, and unless there is a considerable goiter or exophthalmos the true cause of the trouble may not be detected.

The necessity of the recognition of *acute toxic thyroidism needs* considerable emphasis. Though the condition is quite uncommon, I believe that it is by no means so rare as is generally supposed, nor so difficult to recognize after attention is called to it. Judging from the few cases I have seen and known about, this particular condition must have a very high mortality, and yet I believe that of all the different types of exophthalmic goiter this is the most amenable to the serum treatment. The history of such a case usually covers a few weeks of the common vasomotor and nervous symptoms which more or less rapidly become worse and are accompanied by fever until the clinical picture, as Dr. W. G.

---

[*] Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Thompson has described it, is almost exactly that of malignant endocarditis. There are the flushed and sunken cheeks, dry tongue, rapid labored breathing, tumultous heart action, the nausea, vomiting and diarrhea of any toxic state and often thromboses or extravasations of blood in the neighborhood of the peripheral vessels. There may also be enlargement of the liver with pain and evidence of perihepatitis. The terminal stages are accompanied by delirium and finally coma, and as the urine may contain albumin or sugar the possible errors in diagnosis are evident. There is usually no exophthalmos, at least there was none in the few cases I have seen, and about the only characteristic feature among all the symptoms is the thyroid enlargement. Without some increase in size of this organ open to detection by sight or touch, I do not believe the correct diagnosis can be made except by the most careful exclusion of all other possible conditions and by the trial of the antithyroid serum. Fortunately the thyroid, though small, is generally at least palpable and this is a valuable guide.

The *psychopathic or neuropathic* forms of thyroidism constitute a small but important group of cases, and when there is taken into consideration the evident poisoning of the nervous system, which is so prominent a feature of this disorder, the only wonder is that pronounced disease of the brain or spinal cord or peripheral nerves does not more often supervene on the usual insomnia and general state of mental and nervous excitation. In looking over the histories and recalling the individuals it is quite possible to trace the progress of the psychic changes from the mild forms of alternating exaltation and depression through a melancholic stage to pronounced delusions with homicidal tendencies. Of two bad cases of this description which I have seen, one after recovery and the other in the intervals of the malady, could recall to memory all their disordered imaginings and acts and were more or less aware of their disordered character during the period in which they suffered from mental derangement, but they were controlled by overpowering impulses. In the beginning these patients ought to be curable; but after organic changes in the nervous system have occurred any great improvement is probably impossible.

A SPECIFIC SERUM.

The preliminary report on the treatment of exophthalmic goiter by a specic serum published in February, 1906,[1] contained statements which must now be somewhat modified. The serum is made by separating the nucleoproteids and thyroglobulin from the human thyroid gland and injecting these bodies into the peritoneal cavities of rabbits, dogs or sheep. The inoculations are continued at intervals of from five to six days for about six weeks and the animals are then bled from the carotid. The serum thus obtained presumably contains an antibody or cytotoxin which is specific in its action on the thyroidal epithelium and an antibody or antitoxin for the thyroglobulin which is believed to be the active and, in diseased states, the toxic product of the gland. I formerly attempted to draw some clinical distinction between the antitoxic and cytotoxic elements in the serum, but more extensive experience has shown this to be probably erroneous. Hence, as the antitoxin has at the best a more or less theoretic existence, while the cytotoxin can be demonstrated in the test tube and all the clinical phenomena can be explained by the action of the cytotoxin which is certainly present, I shall mention only the cytotoxin.

Nevertheless, a serum made by excluding all the globulin and using only the nucleoproteids from a pathologic thyroid (exophthalmic) seems at least dangerous (Case 38), while neither the normal nor the pathologic serum made in the usual way by combining the nucleoproteids and thyroglobulin in the injections has produced, at the worst, anything more than severe symptoms.

Early in our experience the need of some means of standardization of the different sera became apparent, and Dr. Beebe devised an agglutinin reaction by which an estimate could be made in any given sample of serum of its cytotoxin activity. The complicated details of this test will be found in his article; it is enough to state here that minute fragments of human thyroid gland suspended in salt solution can be agglutinated by a specific antithyroid serum in a manner quite similar to the agglutination of typhoid bacilli in the Widal reaction. The more pronounced and rapid is this antithyroid agglutination the more effect will the serum exhibit clinically, although, unfortunately, this is not a very reliable therapeutic guide. Nevertheless, it is of considerable assistance in judging of the presence or entire absence of any active constituent in the serum yielded by any particular animal. In other words, some animals were found to yield a serum which gave no agglutinin test and in such instances the effect on the patient was entirely negative. At the same time it was demonstrated that only a large gray buck of the Belgian hare species of rabbit could be at all relied on; white rabbits have been found to be of practically no use. The dog, which in respect to the quantity of serum obtainable would be a very desirable animal, produced a serum showing in the test tube slight activity; but the sheep was considerably better, although a great quantity of thyroids were required for the inoculations; and the material used for immunizing purposes is not inexhaustible even if its character which, I believe, is a very important factor in the results, is not considered. For the sake of brevity in description, I shall call the serum obtained by inoculating rabbits with the combined nucleoproteids and thyroglobulin of the pathologic thyroids of this disease, the pathologic serum. For our supply of these glands we have to thank Dr. Charles Mayo, of Rochester, Minn., who has kept us pretty well provided with the organs he has removed at operation.

By normal rabbit, dog or sheep serum is meant an antitoxic or antithyroidal serum obtained by inoculating these animals with the combined nucleoproteids and thyroglobulin separated from the normal human gland.

It is worth noting at the same time that the nucleoproteids in the pathologic gland are in far greater abundance than in the normal gland, and, as the character of these proteids may differ from the normal, so there may be some difference in the serum which can not be detected chemically, but which when tested clinically does produce a different result. At first the normal serum seemed entirely unsatisfactory and the pathologic serum appeared to be the only hope, but now, fortunately, the discrepancies between the effects of the two sera have not been found to be so great as was formerly believed. The normal serum generally shows a less active agglutinin reaction than the pathologic and those specimens of sera which may be considered of maximum activity have only been obtained from one or two out of a great number of rabbits and then were made by inoculations from the pathologic gland. In the administration of the different sera a certain proportion of the patients hitherto have not reacted at all to the normal serum, or if they did the result has appeared harmful rather than beneficial, and a few patients have not improved unless given the very best grade of pathologic serum which can be obtained only from exceptional animals. There is much yet to be learned, however, both about the dosage of any given serum and the frequency of its administration, and I have hopes that the normal serum can be made effective in a much greater proportion of cases than it has been in the past. For if a change for the better can once be established in a patient's condition the normal serum and even the less active specimens of normal serum have generally proved capable of checking the more or less frequent exacerbations of thyroidism. On the other hand, the normal dog serum, although by the agglutinin test the least active of all the sera, has seemed in a few instances to have given the best results.

---

[1] THE JOURNAL A. M. A., Feb. 17, 1906.

STATISTICS.

Our statistics include a total of 90 cases, of which 23 have been cured of all symptoms of thyroidism, 52 have been more or less improved and 11 have failed to improve (as yet) and four have died. Of the latter, one was an acute toxic case who immediately after the administration of the serum passed from an apparently moribund to a convalescent condition, but later, as the recovery was very slow, I operated on her with a fatal result. The second was in a chronic toxic state and, after improving under the administration of the serum, went home and some six weeks later suddenly dropped dead. At the autopsy there was found a pronounced status lymphaticus. The third case, one of the very acute toxic type, died, after improving in pulse, respiration and temperature, with every evidence of a hemorrhage into the respiratory center and, I think, in spite of the serum and not because of its administration; too little apparently was given to prevent the toxemic extravasation of blood. The fourth patient was losing ground and died soon after the administration of the serum, which in this instance differed from the other sera in that it was made only from the nucleoproteids, and hence was a pure cytotoxin (Case 38).

In the 54 personally treated or supervised cases, 15 patients have been cured and 29 improved; six cases were failures and four deaths occurred. In many of the improved cases the patients, I think, are really cured, but as several months must elapse before the result can be determined they can not yet be passed on, and the same can be said of those which have apparently failed. I have several times been surprised to find patients whom I have dismissed as unbenefited after a short trial return a few weeks or months later showing considerable change for the better. I believe, therefore, that if even the slightest improvement in almost any one subjective or objective symptom can be detected within the first two weeks of treatment there is a fair prospect of ultimate cure. If a patient does not at first respond, different grades of sera should be tried, as well as sera from different species of animals, and, if possible, that which I have called the pathologic serum; by varying the dosage and intervals and noting the results much more success can be expected than under any other method of treatment.

PROGNOSIS.

In judging the probable results of the injections the most important factors to be considered are, first, the kind of thyroid possessed by the patient and, next, the duration of the disease and its clinical type. Histologically it is possible to recognize four fairly distinct types of gland; one of these shows increased vascularity, another simple hypertrophy with increase of colloid, and another great increase of epithelium, while in the fourth type there is a marked anatomic change with a loss of the greater part of the thyroid structure. The last represents the terminal stages of a chronic thyroidism and is probably hopeless from a therapeutic standpoint. Some clinical distinction can also be drawn between these different kinds of thyroids. Patients who have soft thyroids respond more easily to the serum than the patients with hard glands and, as a general rule, the smaller the organ the better is the prognosis. The large, hard glands with an irregular and nodular surface, especially if the superficial veins of the neck are numerous and dilated, are, I believe, incapable of much, if any, betterment and belong in the fourth histologic class.

As to the type of the disease, the acute toxic cases with fever seem to do the best with the least serum and at the same time they show the least reaction; and there also seems to be little difference whether the normal or pathologic serum is used, provided, only, it is known to possess considerable activity by the agglutinin test. Apparently this is because the thyroid has not had time to become greatly altered and is approximately of normal structure. I think, however, that the pathologic serum is a little better than the normal for these cases, but the difference is so slight that it is well within the limit of error in observation. But all the chronic forms of the disease respond better to the pathologic than they do to the normal serum and, although the distinction is far from being exact, the variation in the kind of serum required points to the probable condition of the thyroid. As a general rule the more nearly normal it is the better will the normal serum act.

The chronic toxic types of the disease with severe symptoms both of thyroidism and of the secondary lesions dependent on disturbed circulation present the worst prognosis and are the least amenable to this or, in fact, to any form of treatment. The thyroids of these patients are generally large and hard and of irregular outline and the veins of the neck numerous and dilated. As histologically there is very little of the original gland structure left in these cases, it is difficult to conceive of any benefit from a specific antithyroid serum. Nevertheless, one such patient (Case 34) for a time at least improved.

Of the atypical chronic class, those whose chief complaints have been disordered digestion accompanied by fermentation, abdominal or thoracic pain and bad tachycardia, have also generally proved therapeutic failures. The psychopathic and neuropathic cases must, of course, have a poor prognosis unless the original toxemia can be checked before organic nerve lesions have been produced.

THE REACTION TO INJECTIONS.

The reaction to the injection of the serum is of two distinct kinds. One is fortunately rare and occurs within about five minutes of the injection. There is a sudden dilatation of all the superficial capillaries; this "blush" may be succeeded by cyanosis and is accompanied by a feeling of distressing dyspnea and faintness with rapid and feeble pulse; nausea and vomiting and diarrhea follow. These somewhat alarming symptoms pass off in an hour or sooner, if diffusible stimulants are administered, but the patient remains weak and uncomfortable for about a day.

The other reaction is fairly constant and, as a general rule, seems a necessary preliminary to the subsequent improvement. At the point of the injection there is immediately some burning sensation which is followed within a few hours by considerable swelling and erythema which may extend from the shoulder to the wrist when the injection is made in the arm, and continues for several days. This erysipeloid edema has sometimes been much more pronounced with the pathologic than with the normal serum, but the pathologic serum, though causing greater local redness and swelling, gives rise to less pain than the normal. Then at about the same time or some twelve hours after the injection there is generally some fever with increase in the tachycardia or irregular heart action and often diarrhea which may last a day or so. If another injection is given in the other arm before the subsidence of the swelling in the first arm the latter will be made worse and the constitutional symptoms intensified. Indeed, I believe by pushing the serum or gently increasing the dose there might be produced a fatal result. At all events, by repeating the dose too often the patient can be so exhausted that harm rather than good is the immediate consequence. In only a few instances have I seen this constitutional reaction postponed till the end of five or six days; and then it seemed to be connected with menstruation, which began in these particular patients about that time. For the serum, if administered just before or at the beginning of menstruation, may cause the ordinary reaction to be increased, and hence the date of the monthly period must always be ascertained and an injection postponed until the flow of blood has at least nearly ceased.

ASSIMILATION OF THE SERUM.

In the administration of the serum the patient should be put to bed for the first week; no restriction in diet is necessary beyond plain wholesome food without stimulants, except in the toxic cases and in patients with diarrhea who will need more or less careful feeding. Then 1 c.c. of a serum which has been proved fairly active by the agglutinin test is given hypodermically into the subcutaneous tissue in the back of the upper arm between the skin and muscular fascia. I have always selected this region, as it is accessible and free from veins and is loose enough to permit of considerable swelling without undue pain or danger of sloughing. The local reaction around the point of injection is best treated by a wet dressing of a 1 to 60 or 80 solution of carbolic acid in water and the constitutional reaction which appears a few hours later, by the administration, every three or four hours, of about three grains of iodid of potassium with about five minims of the tincture of strophanthus. The iodid of potassium has apparently a specific effect on the thyroidism and aids greatly in checking any rapid or irregular heart action. After all signs of the reaction have subsided there should be some improvement in the subjective symptoms. If an active pathologic serum has been employed the improvement occurs a little earlier and is a little more marked than with the normal serum. The restlessness, the feeling of discomfort, the insomnia, and the "thumping" of the heart subsides first and then the pulse becomes slightly slower and stronger. The best results are obtained by giving from four to eight injections of 1 c.c. each every third or fourth day or sometimes at shorter intervals, but waiting each time until the previous reaction has subsided. Some degree of immunity at least to the constitutional reaction seems finally to become established. The acute toxic cases with fever, as stated previously, have not shown any reaction, but after the first day have improved steadily and quite rapidly so there seems no reasonable expectation of any disagreeable reaction in these cases. As they are the most dangerous type of the disease and very apt to prove fatal, especially if they show any degree of cerebral symptoms, the possibilities of the reaction should be disregarded and an active serum pushed by the administration at intervals of 24 hours of 1 c.c. at a dose which may be increased by one-half a c.c. each 24 hours until some noticeable improvement is obtained or until a half-dozen doses have been given.

All the other forms of the disease do not do so well, and some judgment is necessary to determine both the amount of the dose and the frequency of its repetition. About 1 c.c. of an active serum has proved a useful average quantity, but some variation may be required. A small dose of five or ten minims, especially if the serum is not very active, seems to stimulate the thyroid and to make the general condition appreciably worse; and a large dose of 2 or 3 c.c. has produced such alarming symptoms of rapid and irregular heart action that I believe a fatal result could thus be obtained. But within these limits a certain amount of experimentation is necessary; if the usual 1 c.c. dose does not prove beneficial after a couple of trials, 1.5 c.c. or 2 c.c. can next be employed. It will often be found that this change will cause less reaction and more benefit than decreasing the amount. Occasionally, however, .5 or .25 c.c. of very active serum yield the best results; or a serum from another species of animal can be tried. Then after giving some half-dozen injections at intervals of three or four days the subsequent repetitions have to be considered. Too frequent and too long continued treatment seems to do harm rather than good and to produce a condition of muscular weakness and prostration which is as bad or worse than that due to the primary thyroidism. Therefore, the serum should only be administered about once a week for three or four months and after that at longer intervals. Exacerbations of the thyroidism may appear from time to time, but always less and less frequently until finally the patient remains well. As a guide in the administration of the serum a vicious circle hypothesis for the etiology of the condition of thyroidism is of some service. All that is necessary is to break this circle by the inhibitive power of the serum on the thyroid epithelium and then to give no more injections than are demanded to keep it broken until a return to the normal equilibrium is obtained. This seems to require months, but the present indications are that it will occur in the majority of the cases, and I am beginning to have some hopes for even the chronic toxic cases. But a favorable outcome can not be hastened by increasing the quantity or frequency of the dose and, except in the acute toxic cases with fever, which alone are strikingly amenable to this treatment, there is nothing spectacular in the recovery. It is very slow and often intermittent.

The changes in the size and character of the thyroid perhaps better than anything else give an idea of what may be expected as to the rapidity of the general improvement. In the average case the circumference of the neck has shrunken about one-quarter of an inch a month, at first and then remained stationary for some weeks and later again decreased until it reached the normal size in a perfect cure. A thyroid which is smooth and large and rather soft, in other words one which has undergone simple hypertrophy at first softens and diminishes in size quite perceptibly and rapidly, apparently from loss of colloid and congestion. Then there is a long period when very little shrinkage or change can be detected, except a slightly lowered position. During this time it becomes firmer and harder at menstruation or in slight exacerbations of the disorder which generally indicate a repetition of the injection. Later, or at the end of four or five months, it may once more soften and be gradually reduced to a normal size. On the other hand, a thyroid which is hard at the outset shows the first sign of improvement by becoming softer. I do not believe that the large glands, whether soft or hard, ever entirely disappear, for at least one of these patients who has remained entirely free from all symptoms, even the exophthalmos, for several months still has a quite perceptible fibrous goiter. Occasionally also after the administration of the serum patients complain of some soreness or pain in the region of the thyroid or throat but I have never under these conditions noted anything like active inflammation in the gland. Those who have recovered completely have required about six months of treatment and observation before all signs of the disease, or more accurately of overactivity of the thyroid, have disappeared. But if improvement in almost any one symptom, either subjective or objective, can be detected during the first week or two of treatment, even if the pulse or other signs do not respond, the case should not be given up immediately as hopeless. Slight variations can be made in the dosage of the serum or another kind of serum should be tried, bearing in mind that some patients, especially these with chronic toxic or severe symptoms of long duration and generally possessing hard or very vascular thyroids, will not respond at all to the normal serum, but will to the pathologic, or sometimes only to a particular pathologic serum of exceptional activity.

A few patients, especially those in middle life or older, who generally have small thyroids with slight or no exophthalmos and rather severe nervous symptoms, show a somewhat peculiar reaction. They improve in sleep and in the restless discomfort, and then if the injections are continued they become weaker and are made worse than ever. But if as soon as the initial improvement is noted, the injections are suspended and the patient put under the best hygienic outdoor conditions, they will gradually improve very much and at the end of two or three months, treatment can be resumed. It requires considerable judgment, coupled with some experience not to give such cases up as hopeless at the end of the first week, but many of the patients I believe will ultimately recover if patience is practiced along with the regulation rest treatment combined with the serum administered at long intervals. It is possible that some element of myxedema may here be involved and that thyroid feeding rather than antithyroid injections may be indicated.

The convalescence in these as in all the other rather severe forms of thyroidism is very like that from typhoid fever or any other exhausting disease, and is exceedingly slow and often interrupted by exacerbations of the process which should be met with another injection of the serum. But after a patient has once made good progress towards recovery and then shows signs of relapse it is noticeable that almost any normal or pathologic serum, if administered without delay, will stop the symptoms. At the best, a moderate proportion of the chronic cases of this disease, especially those patients past middle age and with hard glands can not be benefited by either the normal or pathologic serum and for these, after a fair trial for at least a month, I think that surgery offers the best hope.

To correct an erroneous impression of this serum which seems to be prevalent, I must repeat that only in the rare acute cases can any quick results be expected and then there is a long period of convalescence before recovery is completed. The majority of the patients respond very slowly and several weeks may elapse before they are evidently improved. I believe, however, that with greater experience in the preparation of this peculiar remedy and with care and patience in its administration many of the chronic cases can finally be greatly benefited if not ultimately entirely cured.

The details of all the histories can be found in The Transactions of the Association of American Physicians of 1906. Only typical examples of two cases are given here and in addition two of the four fatal cases. In the other two fatal cases the patients had first been improved by the serum and the deaths took place long after the cessation of the injections; one from operation and subsequent very acute thyroidism, and the other apparently on account of a condition of status lymphaticus. Of the two fatal cases here given, the first (Case 37), I think, died from an unusually acute and severe form of the disease and not at all because of the administration of the serum.

The fatal ending in Case 38 might with some reason be ascribed to the effects of the serum, although it must be borne in mind that the disease was rather acute and severe and the patient had previously been losing ground. She received a serum made entirely from the nucleoproteids of a thyroid gland taken from a patient who had died of exopthalmic goiter. It differed from the other sera in not having any globulin combined with the nucleoproteids in the inoculations and so should serve as a warning for using great care in the administration of such a serum. I had several times previously given this same serum in much larger dosage (though at not quite such short intervals) and seemingly with benefit to others, but since this experience I have never dared to give a pure cytotoxin at less intervals than five days or a week, as the effect may be cumulative, and cause no symptoms for two or three days.

Case 13.—J. McG., age 27, single, female, has been nervous for years, but first noted typical signs two years ago. She had been confined to bed for a month, with loss rather than gain in strength. There was a moderate-sized soft goiter; neck measured 14 inches in circumference; pulse was from 110 to 130 with throbbing heart and pulsating thorax.

Treatment.—January 12 to 22, she received in divided doses 5 c.c. of normal rabbit serum and 1 c.c. of pathologic serum with slow improvement in subjective symptoms and slightly lowered pulse rate. She left the hospital for home a little stronger, with less heart throbbing and with the neck ¾ of an inch less in circumference. Pulse was 110. After this at intervals at first of four days and later of a week she received injections of different normal and pathologic sera, apparently improving more under the latter than the former and with more reaction. The pulse during March remained about 100 but of good quality. The thyroid was firmer and a little smaller, and she was able to resume work. The last injection was given April 14, and May 6 the pulse was 84, the thyroid small and again soft. The neck 12¼ inches in circumference and the general condition normal. Since the first of March she has been working steadily as an office nurse and stenographer and has been conscious of no physical disability. At present (August, 1906) there is no exophthalmos, no tremor, no abnormal subjective symptoms, the pulse is about 80 and though there is still a slight fulness of the neck, it is so slight that she can be reported as cured.

CASE. 32.—A. P., aged 29, single, Swedish domestic, entered the Presbyterian hospital under the care of Dr. W. G. Thompson, Dec. 11, 1905.

Examination.—She had a temperature of 102, pulse of 120, and respiration of 25 to the minute. There was a slight but perfectly plain, soft symmetrical goiter, precordial heave, marked pulsation in the cervical vessels and evident dyspnea, but no exophthalmos. She was very weak and tremulous, and had some nausea and diarrhea. She gave a history chiefly of this and "nervousness" and sleeplessness for only the past two weeks, and had therefore an acute type of the disease. The condition grew rapidly worse, and December 16 the temperature was 104, the pulse 136 and the respirations 36; the tongue was dry and hard, there were ecchymotic spots in various parts of the body and evident thrombosis in some of the veins of both legs. The picture was one of a severe and probably fatal toxemia.

Treatment.—December 16 and 17 she received 1 c.c. and on the 20th 2 c.c. of a very active pathologic serum and no other medication then or afterward. There was no appreciable reaction and after the second dose there was a very marked improvement in all the symptoms. December 22 the temperature, pulse and respiration were practically normal.

Result.—There ensued a steady through rather slow progress toward recovery. She was up and around the ward in the middle of January with no signs of the disease, except weakness, some anorexia and a soft thyroid which could be felt, but was not perceptible to sight. She left the hospital in February apparently well and when last seen on April 30 was on her way to make a visit in Sweden and presented no sign of disease.

CASE 37.—M. R., aged 18, single, female, first noted a soft goiter in October, 1905. For this she was given thyroid tablets. A month later she fainted in the gymnasium and symptoms of exophthalmic goiter were evident. After cessation of the thyroid feeding the thyroidism subsided but reappeared in December after a tonsillitis. During the next three months she became normal except for a small soft goiter. In April there were again slight signs of thyroidism but these disappeared until on May 4 a severe gastroenteritis occurred after some indiscretion in diet. On May 5 and 6, the signs of Graves' disease quite suddenly recurred and became severe with headache, great restlessness and tachycardia. On May 7 the pulse was counted at from 200 to 210. The respiration was labored and between 30 and 40 to the minute. On May 8, 9 and 10 she received 1 c.c. of a moderately active pathologic serum without any reaction except a slight and transient local redness. The heart action and respiration began to improve on May 9 and on May 11, the pulse was about 90 and good, and the breathing 23 to the minute. The intense headache on May 8 and the restlessness grew worse and on May 10 stupor developed and deepened into coma on May 13, and a right-sided, incomplete hemiplegia was then noted and this was soon followed by Cheyne-Stokes respiration. Breathing then stopped completely about 10.45 a m., and as the pulse continued at from 110 to 120 but of good quality, artificial respiration was begun and continued until 5 p. m. The condition then became worse and the patient died. No autopsy was permitted.

Remarks.—I believe that the cause of death was a hemorrhage into the respiratory center and that the fatal ending took place not because of, but in spite of the serum. The administration of serum should have been begun earlier and pushed more vigorously. It is worth noting that just after respiration ceased at 11 a. m. on May 13, I gave 2 c.c. of an active normal serum in the preparation of which much thyroglobulin was used and hence, theoretically, the serum contained considerable antithyroglobulin. About two hours after its administration there was a noticeable improvement and natural respiration was possible for about 20 minutes. Respiration then again failed and could not be restored.

CASE 38.—A. G., aged 15, single, female, had suffered from typical symptoms of the disease, but with no exophthalmos for about four months.

History.—She entered the Presbyterian hospital in January, 1906, and received all the usual treatment with a steady, slow deterioration. She was given different specimens of serum without any change and reacted only to a very active pathologic serum from one particular rabbit. This reaction consisted in an exacerbation of all symptoms with fever, lasting for about twenty-four hours after the injection and followed by a brief improvement and almost immediately by a recurrence of all characteristic symptoms.

Examination.—May 20, 1906, the pulse varied from 130 to 150. There was a hard symmetrical goiter of moderate size. The neck measured 13 inches in circumference; the heart was dilated and overacting; the temperature ranged between 99 and 101 and the patient was so weak as to be unable to sit up in bed without fainting.

Treatment.—A very active pathologic serum made only from the nucleoproteids of the thyroid of a patient who had died of this disease, was employed. This was used as no other serum had shown the least effect (except one, and that only with transient benefit). At 10 a. m. and at 11 p. m. May 20, and at 10 p. m. May 21 she received 10 minims of this cytotoxin. There resulted only a slight local erythema until the morning of May 26 and then the temperature dropped from 100 to 96, the pulse began to rise rapidly from 130 to 180, and the patient became extremely restless, vomited frequently, and in the afternoon passed into a condition of stupor. On the previous day the goiter, which had been hard, began to soften and shrink, and during the afternoon of May 23 could only be made out as a small soft mass not much larger than the normal gland. The circumference of the neck in these two days decreased from 13 to 11¼ inches. Three c.c. of an active normal gland serum were then administered in the faint hope of averting the apparently fatal result, as the normal serum can be supposed to contain at least some antithyroglobulin. Some hours later the pulse fell from 180 to 120 but the stupor continued and the patient died at 11 p. m., May 23. With great difficulty, the house physician, Dr. Mason, obtained only the thyroid gland, which showed the following changes as described by Dr. James Ewing.

Examination of Thyroid.—The material received for examination consisted of a portion of one lobe of the thyroid removed 2 hours after death and measuring 2.5 × 3 cm. This tissue was strikingly light yellowish in color as though very fatty and anemic; the consistence was greatly reduced; no colloid could be detected except in a very few small cystic areas from 1 to 2 m.m. in diameter. Although in general very anemic, the tissue showed a few pin-point hemorrhages. The tissue was hardened in 80 per cent. alcohol, in Zenker's fluid, and in Orth's fluid. Sections showed the usual changes of an active toxic form of exophthalmic goiter. There were visible marked cellular hyperplasia, many new alveoli, a few miliary hemorrhages, extreme granular degeneration of tubule cells, and extensive exfoliation of these cells. Much of this exfoliation appears to be due to traumatism applied during removal of the gland. Staining by osmic acid after fixation in Muller-formol shows comparatively little fatty degeneration. The colloid is limited to a few large alveoli containing semifluid colloid mixed with many exfoliated cells. The only changes that seem possibly referable to action of the serum are the anemia and the acute degeneration of the cells. Otherwise, the changes do not differ from those seen in the average case of acute fatal exophthalmic goiter.

Philippine Plants.—The *Philippine Journal of Science* issues a supplement dated April 15, 1906, containing a systematic description, by E. D. Merrel, of the flora of the Lamao Forest Reserve, comprising 1,151 species in 611 genera from the musci, vascular cryptogams and flowering plants, but not the fungi algæ and lichens. Four hundred and eighty-five species are trees and 201 shrubs and woody plants. The monograph contains 142 pages, but it is admitted that a large number of species occurring in the district have not been catalogued.

A SERUM HAVING THERAPEUTIC VALUE IN THE TREATMENT OF EXOPHTHALMIC GOITER.*

S. P. BEEBE, M.D., Ph.D.
NEW YORK.

A preliminary paper was published in The Journal, Feb. 17, 1906, describing the preparation of a serum having therapeutic value in the treatment of exophthalmic goiter. Since that date I have had a great deal more experience in the preparation of the serum, and its therapeutic effect has been carefully tried on many more patients so that it is now possible to describe improved processes for its manufacture and to state more nearly what its value is likely to be.

The theoretical basis was described in sufficient detail in the first paper. I may say, however, that since the publication of the article in the *Journal of Experimental Medicine*,[1] describing the experiments which led to the therapeutic application in exophthalmic goiter, I have made many more experiments of the same nature, and as a result it may safely be concluded that a serum having a high degree of specificity can be prepared by injecting the purified nucleoproteids of a given organ into some animal of alien species. The experiments have demonstrated, likewise, that absolute specificity can not be attained by this method, and I believe that no method will enable us to prepare a serum having absolutely specific properties.

At the time of our first report Dr. Rogers and I had used only the thyroid glands from two fatal cases of exophthalmic goiter as a source of the proteids. For theoretical and practical reasons, however, we followed these first experiments by others in which the serum had been developed by proteids derived from normal human glands obtained at autopsy. The method of preparation has been the same in each case and is given in detail below.

PREPARATION OF THE PROTEIDS.

Normal human glands obtained at autopsy are ground to a very fine hash by a special machine. From six to eight times the volume of 0.8 per cent. salt solution is added and the whole thoroughly shaken and allowed to extract for twelve hours in the refrigerator, chloroform and thymol being added to prevent bacterial growth. At the end of this period the coarser particles are removed by straining through gauze, the filtrate is centrifugated and finally filtered to remove the finest particles. The clear filtrate contains three classes of proteids, namely, nucleoproteids, globulins and albumins, the first two of which we wish to use. Nucleoproteids are precipitated by the addition of acetic acid to a frank acid reaction, using litmus as an indicator. I find a very marked difference between normal and goiter glands in respect to this precipitation behavior. It is rarely possible to obtain a definite flocculent precipitate by the addition of acetic acid to the extract of normal glands.

The normal gland contains a very small proportion of nuclear material and a relatively large amount of colloid. The glands can not be obtained in a perfectly fresh condition, the autopsies varying from 12 to 50 hours postmortem and, although the bodies are kept cool, there is opportunity for autolytic changes which readily occur. I have never failed to precipitate nucleoproteids from extracts of perfectly fresh normal glands of sheep or dogs, but it is often very scanty in amount, and if the glands are allowed to remain in a warm place for a few hours no precipitate will form.

Since the object is to obtain both nucleoproteids and globulin for injection, it has been found best to precipitate both together by making the saline extract acid with acetic acid and then to precipitate the globulin by the addition of an equal volume of saturated ammonium sulphate solution. After standing in the refrigerator for a few hours a voluminous precipitate has collected in such form that it may be filtrated out readily. These proteids are twice redissolved in alkaline sodium chlorid solution and reprecipitated by acetic acid and ammonium sulphate solution. After the last filtration the proteids are carefully removed from the paper and dialyzed in a parchment tube for four days with the addition of thymol as an antiseptic. Such a period of dialysis does not remove all the ammonium sulphate, but for the purpose of inoculating the animals there is no objection to the small quantity remaining. At the end of this period, the contents of the dialysis sack are made feebly alkaline with sodium carbonate, and the solution which contains the desired proteids is kept in the refrigerator. Just before injection, the solution is filtered and a definite quantity measured out. The final filtration removes all fragments of thymol, shreds of filter paper and any undissolved material remaining after the dialysis.

The above method applies only to those proteids which I have obtained from normal glands and is given in detail so that no one familiar with the simplest manipulations in physiologic chemistry will have difficulty in following them. In some instances the same procedure has been followed in dealing with the exophthalmic goiter glands.[2] In other cases we have tried to determine how a serum made from the nucleoproteids alone would compare with that made by including the globulins. For this purpose we have prepared nucleoproteids after the same method that was followed in preparing them from the organs of dogs, namely, by repeated precipitation with acetic acid, accompanied by careful washing. The saline extract is prepared in the same manner as with the normal glands, nucleoproteids precipitated by the addition of acetic acid and the precipitate allowed to settle in tall, narrow glass cylinders, washed by decantation until the supernatant fluid is free from proteid and then dissolved by the addition of sodium carbonate to alkaline reaction.

After filtering this solution the nucleoproteid is precipitated by acetic acid and the process of washing repeated. The final product in some instances has been dried at a low temperature in a special apparatus, which has been described elsewhere. Such dried proteid may be kept for an indefinite time without harm. In other instances the nucleoproteid precipitate has been kept in tubes in the refrigerator with the addition of chloroform as an antiseptic. When this proteid is desired for injection it is dissolved by the addition of sodium carbonate to a faint alkaline reaction to litmus. It is of some importance that this reaction be carefully determined. If the injected material is acid in reaction, or if the reaction is too strongly alkaline, a fatal peritonitis is likely to result. In some instances it happens that the nucleoproteids dissolve very slowly and incompletely on making the suspension alkaline. Such a condition does not prohibit the use of the proteid, however, for I have found that an active serum can be obtained from its injection.

[1] Beebe: Jour. of Exper. Medicine, November, 1905.

[2] It is a pleasure to record here our obligations to the Drs. Mayo for their courtesy in furnishing us with glands at operation, and also to Dr. L. B. Wilson for his painstaking care in packing them for shipment. Without their assistance it would have been impossible to do much of the work which is now reported.

INJECTION OF THE ANIMALS.

Three species of animals have been used for developing the serum, namely, rabbits, dogs and sheep. By far the largest part of the serum has been made in rabbits, but we have been using sheep in the more recent work for experiments with the normal thyroid proteids. For some unexplained reason, dogs have not yielded an efficient serum and their use has been discontinued. It is not possible to predict the activity of a serum which any given animal may produce. The factor of personal idiosyncrasy is noticed here, as in most matters relating to immunity. Serum has been obtained from a large number of rabbits, both for the thyroid experiments and also in continuation of the work on cytotoxins, and it is possible to say as a result of it that the best serum can be produced in a certain type of animal, namely, large buck Belgian hares. The animals should be full grown young adults, weighing from six to eight pounds, and should be well fed and cared for throughout the immunization period. It occasionally happens, however, that an animal in what appears to be prime physical condition and having the best care fails to produce an active serum. Investigators who wish to repeat these experiments should bear these facts in mind.

The injections have been made into the peritoneal cavity. Subcutaneous injections almost invariably result in abscesses. The technic is simple. A small area on the abdomen is shaved and a small needle hole burned in the skin with a hot wire. A short needle with a dull point should be used to avoid puncturing the intestines. The amount of material injected is determined to a considerable extent by the behavior of the rabbit, particularly with respect to the loss in weight. In general, however, the proteid from 10 grams of thyroid is employed for an initial dose in a six-pound rabbit, and the subsequent doses determined by the loss in weight. The sheep, which in the beginning weighed 125, have had injections of 100 cubic centimeters of solution, an amount which represents the proteid from 80 grams of normal human thyroid gland. One of these sheep has been bled four times and has had in total the proteid from more than 700 grams of normal human thyroid gland during the period from December 20 to May 4. With the rabbits, five injections, six to eight days apart, have been given and the animal exsanguinated from the carotid on the eighth day after the last injection. The sheep have been bled after analogous treatment, but quite enough serum can be obtained without exsanguinating the animal. After three additional weekly injections the animal may be bled again. The treatment is a severe experience, however, and must be given cautiously.

PROPERTIES OF THE SERUM.

At the time of our first publication Dr. Rogers and I had employed no means of testing the activity of the serum except its direct inoculation into patients having exophthalmic goiter and noting the reaction produced. The method of standardizing diphtheria and tetanus antitoxins can not be successfully applied in this case. Later in the work, when I came to the point of testing the agglutinin and precipitin reactions on thyroid fragments and proteid, respectively, it occurred to me that we could use these means for standardizing the serum if it proved that the agglutinating action was in some constant degree parallel to the therapeutic effect. To determine this point I tested many different sera which had been in the laboratory for some time, and which had been thoroughly tested clinically. The results proved to be nearly uniform and were sufficiently promising to lead to a continuation of the study on these lines. In general, it has been found that the more active the agglutinating powers the more marked the local and general reaction following injection. Here again the personal idiosyncrasy of the patient enters, and we find that a serum that agglutinates well produces a vigorous reaction in most patients, but such a result is not invariable. In order to have comparable conditions a definite method has been followed in making these agglutination tests.

Twenty-five grams of normal human thyroid, which have been pulverized in a special machine, are extracted for two hours in 100 c.c. of 0.8 per cent. salt solution; the extract is next strained through gauze and centrifugated for four minutes at uniform speed. Such treatment precipitates the coarser particles firmly in the bottom of the tubes, while the finer fragments remain in looser suspension below the clear extract, but above the coarser impacted mass. The finer particles can be separated with a considerable degree of sharpness from the coarser, and after diluting with 0.8 per cent. salt solution to 250 c.c. and straining through cotton a suspension is obtained which in many ways can be compared to a bacterial emulsion. In the ice box or incubator the fine particles settle very slowly, and in a manner quite different from the agglutinating action which is obtained by the addition of a specific immune serum. In order to have comparable results, it is necessary to follow the method of preparation of the emulsion with some considerable care, for I have found that the time and completeness of the agglutination depend in no small degree on the concentration of the suspension.

As regards the serum, the time required depends on two factors, namely, the potency of the serum and its concentration. The method we have followed is to prepare several tubes containing the same suspension of thyroid cells, to add varying quantities of immune serum and to incubate at 38 C. By noting the length of time required to produce the flocking in various concentrations of serum we can form an idea as to the relative activity. Such tests made under comparable conditions with a large number of sera show that the agglutinating power is in a remarkable degree parallel with the vigor of the local and the constitutional reaction produced by the serum on injection. In this respect, it may differ from bacterial antitoxins in that the latter are not supposed to show any definite relations between their agglutinating and bactericidal and antitoxic properties. I do not wish to be understood as saying that the most active serum will effect a cure in a shorter time than the weaker; there are many other factors involved beside the simple antagonistic action of the serum for a toxin.

Another point of considerable interest is the fact that the serum is highly specific in its agglutinating properties. Suspensions of other human tissues, such as muscle, liver, lymph gland, round-cell sarcoma, are not agglutinated except occasionally by high concentrations after long standing. A serum which in a concentration of 1 to 2 agglutinates thyroid fragments in 30 seconds shows very feeble agglutination of muscle fragments in ten hours. After such a lapse of time it is often difficult to distinguish flocking from mere settling, but the supernatant fluid is somewhat clearer in the tubes to which the serum has been added.

HEMOLYTIC PROPERTIES.

In the first paper dealing with cytotoxic serum, I stated that there was no reason for believing that the action was due primarily to hemolysis or hemagglutinative properties which were demonstrable in strong concentration in test tube reactions. Histologically, we could find no positive evidence that would lead us to such a conclusion, while experiments *in vitro* showed that in such a concentration as the serum was used *in vivo* no hemolysis or hemagglutination was evident. The therapeutic dose of thyroid serum has never approached nearer than 1/100 of that used in the dog experiments, and it is hardly possible that this is a concentration sufficient for the feeble hemolytic property to show itself. We have no satisfactory evidence, however, that the results of test tube experiments apply in the body, and it is conceivable that a serum may be hemolytic *in vivo* in much more dilute concentrations than are required *in vitro*.

We have had some opportunity to test the matter clinically and have found that the serum treatment generally causes an increase in the per cent. of hemoglobin and number of erythrocytes. Such a result may be due to the general improvement in health and probably not to a direct effect on the blood-forming organs. These clinical results, however, are based on too few cases to be considered final.

THERAPEUTIC EFFECT.

It is a matter of much interest to consider how far our primary objects can be attained by the use of the serum. Our laboratory experiments have shown that it has highly specific action on the thyroid tissues and that it is not markedly hemolytic, but its real specific antitoxic and cytolytic action must be determined by animal experimentation. We have had human subjects for most of this work, and fortunately only one patient on whom the serum has been used has thus far died, so that our conclusions must come from the clinical results. The serum is based on the theory that exophthalmic goiter is a toxemia and that the toxin in question is the thyroglobulin. If we find that administration of the antiserum causes an immediate and striking improvement in the toxic condition we may reasonably infer that it is due to a neutralization of toxin. In a few severe cases we have noticed a striking improvement in all symptoms follow within forty-eight hours. Such, for instance, occurred in Case 7 in Dr. Rogers'[3] report already printed. This patient is now perfectly well. Cases which show such behavior are generally those having an acute development with a soft thyroid gland, which is probably in a condition of simple hypertrophy and contains a large amount of colloid matter with but little relative increase in the number of cells. Such facts are best explained by the toxemia hypothesis, and constitute the only positive experimental evidence we have for the belief that the serum contains a true antitoxin.

It must be stated, however, that only a small proportion of the cases show the striking immediate improvement which is suggested above. The majority show slow gradual improvement which, although positive and undoubted, does not afford such convincing evidence of antitoxic action. The majority of cases which we have treated have been of the slow developing chronic rather than the acute type. The gland in these cases is more cellular and presumably the cytotoxic element in the serum, in the comparatively feeble doses in which it is administered, can not act with sufficient vigor to cause immediate and rapid diminution in the gland. More rapid destruction might possibly result in a dangerous acute toxemia from the decomposition products of the gland. It is a well-known fact that manipulation or massage of the gland is likely to be followed by an exacerbation of symptoms. It would not be desirable to produce the same class of lesions in the thyroid that were found in the livers and kidneys of the dogs treated with specific cytotoxins, but we do wish to inhibit the gland and to bring its activities back to the normal. Accordingly, a much smaller dose should be used. I confess that I feel much less sure of my ground in dealing with the cytolysin than I do with the antitoxin idea.

There is, however, some evidence which should not be ignored. My previous work with dog organs demonstrates that it is possible to develop highly specific cytotoxic serum from nucleoproteids, and, since these proteids from the thyroid gland are included in the injection, a similar property of the serum should be produced as in the former case. I have had some indications that a partial suppression of kidney function may be produced before we have positive evidence of a kidney lesion resulting from the administration of a nephrotoxin.

Aside from this, I know of no facts which show that inhibition of function may precede lesion. We do not know to what extent it is necessary to injure an organ by such means in order to inhibit its function. It is a purely hypothetical assumption, but it may be easier to inhibit a tissue which is maintained in a habit of excessive unstable activity than it is to affect one in a stable physiologic condition. For instance, the antipyretics reduce fevers, but have little or no effect on normal temperature. A pathologic and a physiologic condition are not precisely comparable. The main fact, however, is that the administration of the serum causes a decrease in the size of the gland and in a few cases it has been restored to apparently normal size. A vicious habit has somehow been broken and it has seemed to me reasonable to ascribe the result in part to the cytolysin properties of the serum.

There is some advantage in having the antithyroid serum developed in two animal species. In some cases the sheep serum, which is developed from normal glands, has been given at weekly intervals for from eight to ten weeks in chronic cases. It was efficient in suppressing the symptoms and caused much improvement, but at the end of this period there were exacerbations which the sheep serum, even in increased doses, would no longer control, although in the beginning it had proved perfectly satisfactory. The serum no longer caused a local reaction, although this, too, had at first been quite pronounced. It seemed possible that the sheep serum had been continued for so long a period that the patient had developed an anti-antitoxin and was, therefore, to a very large extent immune. When rabbit serum, which gave a weaker agglutinin reaction, was administered to these patients the symptoms were promptly controlled. The immunity to the sheep serum did not in any way interfere with the biologically different antitoxin. The two diseases in which serum has been employed most, diphtheria and tetanus, are both acute and accordingly such a possibility as the formation of an anti-antitoxin has needed no consideration. In those chronic cases of exophthalmos in which serum treatment must be long continued, however, it will probably be necessary to change the biologic character of the serum occasionally in order to prevent such interference.

---

[3] Rogers: THE JOURNAL A. M. A., February, 1906, p. 487.

SERUM FROM THE NORMAL AND THAT FROM THE PATHOLOGIC GLAND.

The results reported in the first communication were all obtained by the administration of serum developed from the pathologic gland. Our more recent experiments have demonstrated that it is possible to develop a serum of high therapeutic efficiency from proteids of the normal gland, and it is hardly necessary to add that these results are of considerable interest to both the physiologist and the clinician. For if we had found that serum from the normal gland was quite inefficient it would indicate the presence of a special toxin in the pathologic gland. It would mean not simply excess of function, but rather a complete change in the character of the secretory activity.

Our results are in accord with the results of chemical investigation, for, as I have stated previously, such study has not revealed any special toxin. It is, indeed. Oswald's[4] belief that the exophthalmic goiter thyroglobulin is poorer in iodin than the normal secretion, but this does not indicate a radical difference in the remaining portion of the proteid. There is a very wide variation in the amount of iodin which the normal gland contains, and it is hardly probable that the iodin variations which Oswald has found in the exophthalmic goiter secretion would so alter the proteid molecule from that of the normal as to render the latter unfit to serve in the immunizing process. The biologic character which is of the greatest moment in the process of immunity is probably given by the remaining portions of the proteid rather than by the iodin group, so that I am of the opinion that the exact iodin content is a matter of small importance for our purposes.

The most active serum which I have thus far developed has come from the proteids of certain glands removed at operations. The activity of this serum has been expressed in its agglutinin reactions, the local and constitutional reaction on injection, and its therapeutic effect. In all three phases it has exhibited the highest potency of any serum yet produced, but I am not convinced that its action shows a difference in quality rather than intensity from that of normal glands. There are reasons which, I believe, explain the particularly good quality of this serum, and these are not dependent directly on its being developed from exophthalmic goiter glands. The glands were removed at operation and were received at the laboratory in perfectly fresh condition and consequently the proteids derived therefrom had suffered little by autolysis; second, the serum was developed in young adult Belgian buck hares which stood the injection very well, and, as I found, this is the particular type of animal that gives the best serum. The normal glands from which the serum is made are obtained at autopsy, and this fact makes it impossible to get them in a fresh condition. Practically all our normal serum has been developed in sheep and these animals do not produce so active a product as the hares. This latter statement holds true, also, for the cytotoxins produced from dog organs. We have had striking and immediate improvement follow the administration of both the normal and the pathologic serum and, in my opinion, the facts do not warrant the conclusion that there is any radical difference between the two. This question is one of the highest complexity and can only be settled by long-continued experimentation on a large number of patients. We must take into consideration the great difference in reaction which patients show to the same serum as well as the considerable differences in the quality of the serum produced by the same class of animals under similar treatment.

If the hypothesis regarding the antitoxic and cytotoxic property and their dependence on the injection of thyroglobulin and nucleoproteid, respectively, is correct, then we should find it advisable to vary the activity of the serum in respect to these two factors in order to meet the indications in the various types of cases. Experiments of this sort are now under way, but we can not as yet make any statement of results. The hypothesis may break at any point and it is not safe to make it too extensive.

It is of interest to consider in this connection the condition of the gland from the one fatal case treated with serum. The case was one of long standing; the patient, a man, had had the disease for ten years and was in extreme condition when admitted to the hospital During his period of treatment, which lasted for six weeks, he made good general improvement in all symptoms. The circumference of his neck diminished three inches during this time. His death occurred a few weeks after leaving the hospital, and at the postmortem the gland was found to have a tough, beefy consistency quite different from the soft condition on entrance to the hospital. Histologic section showed the gland to be very cellular, practically without colloid, and in many places the cells were in a partially atrophic condition, which suggested the beginning of the changes characteristic of myxedema. We have no section of the gland showing the condition at the beginning of treatment, but the change in the consistence and size of the gland, together with the postmortem condition, favor the belief that the gland at first had considerable colloid which disappeared during the course of treatment. In this respect the result agrees with the conditions found by many investigators in the thyroid glands of animals treated with cytolysin serum. The patient was treated with serum made from the normal glands only. Since the above was written we have examined the gland from a second fatal case after serum treatment and have found an extensive acute degeneration of the gland. The patient received small doses of serum at frequent intervals. The gland very rapidly diminished in size and the patient died on the fourth day after beginning treatment.

CONCLUSIONS.

When all the conditions are considered I believe it is fair to conclude that the serum is an agent of considerable value in the medical treatment of exophthalmic goiter. It has been used in all manner of cases in which it was possible to make a diagnosis, and in some cases in which the diagnosis was doubtful. Only a comparatively small percentage of these have been of recent development. A small percentage of trials has resulted in failure, a much larger number in improvement, while an encouraging number of individuals have been completely cured. In making up the statistics which are given here, all the cases of which we have any record have been included. These have covered an area from Maine to California, and in many instances the physician in charge of the case has had no other experience with the disease but the one case immediately under treatment. A number of the patients have begun treatment so recently that it is not possible to make any safe conclusion of the outcome. The number of instances of cure and improvement are so large that they can not be ascribed to coincidence, and under favorable conditions I believe much can be accomplished by careful serum therapy.

THE SURGICAL TREATMENT OF EXOPHTHALMIC GOITER.[*]

FRANCIS J. SHEPHERD, M.D., C.M., LL.D. (Edin.), F.R.C.S.E. (Hon.)
MONTREAL.

The treatment of exophthalmic goiter by operation is a comparatively recent procedure and its usefulness as a means of relieving this serious disease is not yet conceded by all. In many cases operation is contraindicated, while in others operative measures result often in complete cure, or almost always in improvement.

The cause of this disease is not yet sufficiently established, but that many cases are caused by an excess of thyroid tissues is self-evident. Yet in some cases (10 per cent.) it is said there is no enlargement of the thyroid and in many the enlargement is not marked. In some cases, again, enlargement of the thyroid is a late symptom in the disease, while in others the enlargement precedes the other symptoms by months and sometimes years. Goiter has been known to exist for years without producing any marked symptoms of this disease and then they appear. The parenchymatous goiter may be present for some time without giving rise to any symptoms, and the enlargement of the thyroid may only be accidentally noticed, by feeling the collar band too tight, or observing a fulness of the neck when looking in a mirror. Some attribute exophthalmic goiter to atrophy of the parathyroids or their infiltration by fat. In my cases where the parathyroids had been removed with the thyroid they have been found perfectly normal in appearance and not infiltrated or atrophied.

The idea that exophthalmic goiter is due to a disorder of the sympathetic and vagus is now abandoned by almost all, and the operation of excision of the sympathetic ganglia and trunk in the neck for the relief of this disease may now be looked on as an obsolete operation. That the nervous system is involved in the affection goes without saying, but the cause is not in the nervous system, but in the thyroid gland, and the profound effect produced on the nervous system is brought about "by the action of certain substances which find their way into the circulation as a result of deranged function of the thyroid gland"; overactivity of the thyroid, or the secretion of an enlarged thyroid produces too much oxidizing material.

Therefore, the probable cause of exophthalmic goiter is hyperactivity and hypersecretion of the thyroid, and the same condition may be produced by artificially feeding an individual with thyroid extract. It is certain that many patients are cured by the removal of the excess of thyroid tissue, and the natural inference is that the excess of thyroid tissue causes the symptoms in those cases in which this organ is enlarged. It is possible that there may be other causes (and in this connection the thymus can not be ignored) in the production of complex symptoms of this disease, for these symptoms may exist without special enlargement of the thyroid, but where there is enlargement the removal of a sufficient quantity of the gland tends to the cure or relief of the symptoms.

Dr. H. MacKenzie[1] says: "If we could assure ourselves that the disease is nothing more or less than a hypertrophy of the thyroid gland, it would seem that the most rational method of treatment is to reduce the enlarged gland to something like normal proportions by surgical means. But we can not ignore the part obviously played by the thymus in this disease. . . . Unfortunately, the operation is, even in the hands of most skilled surgeons, a dangerous one, and the risks are greatest in the class of cases which respond least to medical treatment."

Partial thyroidectomy does not always cure, perhaps because not enough of the gland is taken away. Kocher advocates removing three-quarters or more of the gland and the ligation of three arteries. Ligation of the thyroid arteries is as difficult as thyroidectomy, but less likely to cure and less dangerous. Curtis recommends it as a preliminary operation to partial thyroidectomy and as a palliative operation. Schwyzer, of St. Paul, reports four cases of well-marked exophthalmic goiter cured by ligation of the thyroid arteries.

B. Farquhar Curtis[2] is still a mild advocate of sympathectomy, but latterly he has been practicing thyroidectomy, and in one case did both operations with good results. Jaboulay's operation of exothyropexy is now never practiced, and in fact Jaboulay himself gave it up for section of the cervical sympathetic. As many deaths occur, strange to say, after sympathectomy as after thyroidectomy. It has been thought that deaths following operation in this disease are due to too much absorption of thyroid secretion, owing to the rough handling of the gland. But in the operation of sympathectomy there is no rough handling. It is well known that individuals with exophthalmic goiter stand operations badly and cases are reported of deaths occurring from so-called thyroidism in persons suffering from this disease after operation on distant parts, such as the pelvis or breast. The cause of death in these cases is almost as obscure as the cause of the disease itself, which may sometimes come on after severe fright or anxiety, and these causes in a well-developed case of exophthalmic goiter are well known to lead to an exacerbation of the symptoms.

THE CLASS OF CASES SUITABLE FOR OPERATION.

I am of the opinion that early operations are the safest and that the class of cases most likely to benefit are not the most severe ones, but those in which the gland is more enlarged on one side than another, in which, in fact, there is a more definite tumor formation, in which the gland is not excessively vascular, and in which the enlargement has preceded the symptoms of Graves' disease by months and perhaps years. These might be called cases of secondary or acquired goiter. Also in those early cases of enlarged thyroid with a mild form of Graves' disease, in which the gland is soft, vascular, and evenly enlarged throughout, here operations are usually most satisfactory, the after-results being decidedly good. The cases in which operation should be avoided are those of large vascular thyroids in which there are definite febrile exacerbations, excessive tachycardia, "with acute dilatation of the heart, precordial distress, gastric and abdominal pain, vomiting and diarrhea, sleeplessness, perspirations, sense of suffocation, great restlessness, edema of the feet—in fact, all the symptoms of toxemia due to thyroidism." (Thompson.)

1. British Med. Jour., Oct., 28, 1905.
2. Annals of Surgery, March, 1906.

It is singular that most physicians are against operative measures, or only consent in a half-hearted way to their occasional employment. It is perhaps because they hand over only the desperate cases to the surgeon, after all medical measures have proved futile. Hector MacKenzie[1] says: "On the whole, I consider the risk attending thyroidectomy too great to justify the operation save in exceptional circumstances." Eulenberg is opposed to operation, and Dr. George R. Murray[3] does not mention it at all. Nearly all the recent medical writers on exophthalmic goiter condemn surgical procedures as being too *dangerous and not always successful* (Collins, Robins, S. Smith).

MORTALITY FOLLOWING OPERATIONS.

A good deal depends on the kind of case operated on, and hence statistics are not of great value. Huntington[4] had one death in nine patients operated on. Ransohoff[5] reports six cases without any fatality. Curtis[6] reported fourteen cases of sympathectomy and thyroidectomy with four deaths, and mentions 136 patients operated on by surgeons, including Kocher, Schultz and Mayo, with 17 deaths. A large mortality, but no doubt in properly selected cases this would be much lower. Kocher's report of 59 patients operated on showed: 76 per cent., cured; 14 per cent., improved; 3.8 per cent., slightly improved; 6.7 per cent., died.

At the German Congress for Internal Medicine, held in April, Kocher reported having operated on 167 cases, with 9 deaths and 72 per cent. of cures. Friedheim, of Hamburg, out of 20 cases, had 15 patients cured and 5 improved.

The diseases having the symptoms complex of exophthalmic goiter, then, may be considered to be of two kinds: One in which the patient is extremely nervous and sleepless, has tachycardia, exophthalmos, pyrexia, tremor and edema of extremities, diarrhea and frequent sweatings, emaciation, and with a large, diffuse vascular thyroid usually not more enlarged on one side than the other, and which has not preceded the nervous symptoms, but has come on with the other symptoms indicative of this disease. This patient may have a dilated heart and perhaps endocarditis if the disease is of some standing; in such cases I should not now operate.

Patients in the second class, although ultimately not distinguishable from the former in symptoms, have had goiter for some years, which is more pronounced on one side than the other, and there is nervousness, excitability, difficult respiration, tachycardia, exophthalmos, tremors, sweatings and moderate loss of flesh. These patients are suitable for operation, and when the overgrowth of thyroid is removed the patient ultimately gets quite well. At first the pulse becomes quieter, nervousness is less, the patient increases in weight and generally improves, the exophthalmos, however, diminishes very slowly. Some of these patients operated on nine or ten years ago still remain quite well, and in this class of cases I have had no death following operation, though in some I have had some very alarming symptoms.

Huntington says: "We can not escape the conviction that general anesthesia is in a very large proportion of cases seriously at fault. There is no difference of opinion among operators as to the impropriety of general anesthesia in this relation and especially in advanced cases." Now, I have always used general anesthesia, latterly ether and chloroform mixed, and have had no bad results. In the two cases of death the patients perfectly recovered from the anesthesia and died after some time—eight hours in one case and two days in the other. The danger is always great in operation in a severe case of exophthalmic goiter, but not greater probably than the mortality would be if the patient were treated by medical means only. In selected cases this danger ought not to be very great, and with more extended experience in the cases proper for operation and if the operation is performed in the early stages, in the future I am sure the results will be much better.

REPORT OF CASES.

In the seventeen cases I report there were three deaths, all in desperate cases; nine patients were completely cured; three much improved; one relapsed and one was lost sight of, though improvement was noticed immediately after operation. Four cases were of the cystico-colloid variety; eleven colloid adenoma, and two pure hyperplasia without as much colloid as in the normal gland.

In two cases there was no exophthalmos, though the other symptoms were marked. In two the exophthalmos was slight, and in thirteen it was well marked. The patients' ages ranged from 14 to 53 years, and the average was 28.80. There were sixteen females and one male. All the patients demanded operation for the relief of their distressing symptoms, and in none was the operation insisted on. In every case the dangers were distinctly placed before the patient and her friends.

The following is a synopsis of the seventeen cases:

Case 1.—Mrs. H., aged 35, telegraph operator, always lived in Canada.

History.—Seven years ago she first noticed enlargement of the thyroid, which increased slowly until six months ago, when the gland began to grow rapidly and nervous symptoms were much increased.

Examination.—She entered the hospital for operation Dec. 16, 1894. At that time she had a pulse of 120, tremors, great excitability and loss of flesh with exophthalmos. She had been forced to give up her occupation on account of nervousness, and had also of late experienced some difficulty in breathing. There was enlargement of the thyroid, more on left side, and many hard nodules were felt in this lobe.

Treatment and Result.—The left half of the gland was removed with much benefit. Tumor after removal was found to consist of large vesicles filled with colloid and lined with flattened epithelium. The patient resumed her occupation, had little tachycardia and much diminished nervousness. Several years later I saw her again, when many of the old symptoms had returned, but she refused further surgical interference.

Case 2.—Miss L., aged 20, was sent to me by Dr. Cornell, of Brockville, Ontario.

History.—She has had enlargement of the thyroid for some years; both sides are enlarged and have the appearance of localized tumors. A short time after she noticed the increased size of the gland, nervous symptoms developed, tachycardia, tremors, etc. These symptoms increased on exertion and her pulse was almost uncountable. Then came exophthalmos with persistent pyrexia and on exertion great difficulty in breathing.

Examination.—When I saw her in 1896 she was a pale, anemic girl, very thin, with slight exophthalmos and a rapid pulse, 140 to 200. She was excessively nervous, had tremors, some fever and edema of the extremities, and was much emaciated. Both lobes of the gland were considerably enlarged. The enlargement was not of the soft, diffluent character usually seen in Graves' disease, but was hard and seemed to be a growth well defined on each side and the size of a small orange.

[4] Transactions of the American Surgical Association, 1905

[5] Lancet-Clinic, June, 1905.

[6] Annals of Surgery, March, 1905.

Operation.—Nov. 18, 1896, I enucleated from each lobe by separate incision a solid tumor, the size of a tangarine orange, full of colloid matter.

Result.—The patient rapidly recovered and was sent home in ten days. Two years after she was perfectly well and had no signs of exophthalmos or tachycardia; in fact, all the symptoms for which she consulted me had disappeared. I heard from her in March, 1906, and she still remains perfectly well and has no signs of goiter or Graves' disease. This case was one of my most successful.

Case 3.—Miss McC., aged 24, always lived in Montreal.

History and Examination.—She had a well-marked enlargement of the thyroid, more on the right side. It seemed to be a large solid tumor and commenced three years previously as a small nodule in the middle line of the neck and was supposed to be due to pressure of a brooch. Nervous symptoms appeared with the tumor. She was extremely nervous, had tachycardia (pulse 120), tremors, went upstairs with difficulty, sweated easily, had a slight cough; legs were edematous; she had lost much flesh and had exophthalmos.

Operation and Result.—Oct. 8, 1901, half the gland was removed and the patient made a good recovery. When last seen, three years after the operation, she was attending to her business as a milliner and was quite well, and though at times very nervous she had gained much flesh and the palpitation and other symptoms had disappeared. I have heard lately (April, 1906) that she still remains quite well. The gland was cystico-colloid with hyperplasia.

Case 4.—Bridget McC., aged 16, had enlarged thyroid for four years.

History and Examination.—The enlargement was general, but not very soft or vascular. She was extremely nervous, had tachycardia, pulse 120, tremors, loss of flesh and slight exophthalmos. Two sisters and a brother have enlarged thyroids.

Operation.—At operation the whole thyroid was removed, except a small portion over the trachea.

Result.—The patient rapidly recovered and lost in the course of a few months all nervous symptoms, and when last seen, four years later, was stout, healthy, with no nervous symptoms, and following the occupation of a domestic servant.

Case 5.—Jennie K., aged 24, since she was 15 years of age had enlargement of the thyroid.

History.—It commenced as a small round growth in the right lobe and had continued to grow ever since. For some years, owing to tachycardia and breathlessness, she had not been able to walk upstairs or to walk any distance on the level. For some years also she had had tremors and exophthalmos. The tumor was of large size, smooth, soft and not very vascular. The patient had become much thinner of late.

Operation.—Jan. 27, 1899, the tumor was enucleated. It was cystico-colloid. After operation there was a temperature of 104 F. and an uncountable pulse, with excessive nervousness. The discharges from the wound were sterile; on removing the packing and the evacuation of a large quantity of clear serum the symptoms subsided.

Result.—She was discharged from the hospital much improved, the tachycardia was less, she had no tremors and was altogether better. Six months later she wrote me that her heart had ceased to palpitate and that she was gaining flesh rapidly. In June, 1903, three and a half years after operation, I saw her again and she was looking very well; there was no trace of enlarged thyroid, but she still had slight exophthalmos and was occasionally nervous. I have heard since that she is married.

Case 6.—Miss S., aged 40, first noticed a small swelling on the left side of the neck ten years ago, which has been growing ever since.

Examination.—She had marked tachycardia, tremors, breathlessness on exertion, exophthalmos, and was emaciated and excessively nervous: pulse ranged from 108 to 110. The tumor was of considerable size and confined to the left lobe and isthmus.

Operation.—She was operated on Feb. 23, 1899.

Result.—For a time there was no improvement, but after six months there was less tremor and nervousness. Six years after I heard she was very well, but still has slight exophthalmos.

Case 7.—Miss M., aged 29.

History.—Two years ago her neck began to enlarge on the right side and the swelling gradually increased in size to that of a tangarine orange. She had tachycardia (pulse 120 to 130), tremors, palpitations, breathlessness and hacking cough.

Operation.—August, 1901, operation was uneventful; the right lobe was removed. The patient was much improved by operation and the pulse soon after came down to 90. I have been unable to trace this patient.

Case 8.—Alice H., aged 22, has had an enlarged thyroid all her life; up to three years ago she lived in Ireland.

History.—Latterly the gland has enlarged rapidly and nervous symptoms have been present for the past two years; the enlargement is more on the right side, smooth and vascular, pulsating. The pulse ranged from 100 to 120, the eyes were prominent; there were tremors, edema of legs, palpitation, insomnia, and latterly she has lost much weight.

Operation.—In May, 1904, the right half of the thyroid and isthmus were removed. Symptoms of thyroidism developed after operation; there were high temperature, great restlessness and uncountable pulse. These symptoms subsided at the end of a week and she was discharged at the end of two weeks.

Result.—Three months later I saw her and she had gained over 20 pounds in weight; the pulse was between 70 and 80, and she had resumed her occupation of nurse. Since then she has married and is now very well.

Case 9.—W. M. L., aged 44, had had an enlargement of the right lobe of the thyroid for some seven years.

History.—Seven months before consulting me nervous symptoms commenced to appear with attacks of dyspnea, dry cough, loss of weight, and "protrusion of the eyes." He also had attacks of palpitation and had tremors. Pulse ranged from 110 to 120.

Examination.—A marked enlargement of the right side of the thyroid was found which was soft, diffluent and pulsating. The trachea was displaced to the left. There was a good deal of exophthalmos, more on the right side, with tremors and a pulse of 112.

Operation.—Aug. 9, 1904, the right half of the thyroid and the isthmus were removed. After operation there was great restlessness, rapid pulse, and high temperature, with insomnia: eight days after there was much less nervousness and less tremor.

Result.—Six weeks after he left the hospital he reported himself much better.

Case 10.—Mrs. P., aged 34, was sent to me by Dr. Alguire, Cornwall, Ont.

History.—For the last twelve years she had noticed the thyroid enlarging; it came on soon after her marriage and especially grew during her last two pregnancies; her mother had enlarged thyroid and two of her sisters have it now, one of whom I have since seen has well-marked Graves' disease. The patient had great difficulty in breathing, but none in swallowing. She had tachycardia, pulse 134, exophthalmos, attacks of palpitation, and was very irritable. She had also lost flesh. She had a short, dry cough and of late her voice had altered.

Examination.—Paralysis of the left cord was found. The growth, which was a very large one, commenced on the right side and this is yet the largest part.

Operation.—Nov. 22, 1905, the whole gland was removed with the exception of a small part of the right lobe over the trachea. The trachea was found to be scabbard shaped. After operation, which was a difficult one, hoarseness and dysphagia followed, and then an attack of jaundice ensued, which had not completely disappeared when she left the hospital fourteen days later. With the jaundice her pulse fell to 76.

Result.—I heard from this patient a year after operation and she reported very slow recovery and still had some discomfort with dyspnea, but was gradually improving and had gained flesh. There were no signs of myxedema.

Case 11.—Mrs. H., aged 53, had had enlargement of the thyroid for some years.

History.—She had become so very nervous and excitable that she insisted on operation. She was a thin, excitable woman, with a pulse ranging from 125 to 135, tremors, insomnia, and slight exophthalmos. On each side there was a much enlarged, soft, diffluent and vascular gland; the arteries were very atheromatous.

Operation.—Oct. 19, 1901. Ether anesthesia was used. The patient, on coming to the operating table, had a pulse of 200. The whole gland was removed. The patient stood the operation well and recovered perfectly from the anesthesia, but that evening the pulse became uncountable, the temperature rose rapidly, she was very restless, and died the next morning, evidently from thyroidism.

Case 12.—Mrs. C., aged 30, had had a "full neck" ever since she can remember.

History.—Four months before consulting me, after the birth of her last child, the right lobe began to enlarge and severe nervous symptoms began to develop.

Examination.—When I first saw her I found a small, very excitable, emaciated woman with excessively prominent eyes, and with a pulse of from 140 to 150, and well marked tremors, she was also sleepless and had diarrhea and sweatings. Her husband said that at times she was quite maniacal. She had an enlarged neck, measuring 35 cm., the enlargement greater on the right side. The gland was soft, very vascular, diffluent and pulsating.

Treatment.—I first gave her potassium iodid in ten grain doses. This seemed to have the effect of hardening the gland and she was less nervous, but soon tired of it and refused to take any more. I then tried *x*-rays; six exposures caused diminution of the tumor from a circumference of 35 cm. to 32.5 cm., but there was no perceptible effect on the nervous symptoms. Operation was demanded, and, although I was not very eager to comply, I took her into hospital and kept her in bed for a week with an ice bag on the heart. I had much difficulty in keeping her in bed as she was at times violent and almost maniacal, and seemed in great fear. The left cord was partially paralyzed.

Operation.—Jan. 25, 1906, she was operated on. There was much difficulty in giving the anesthetic, but when she became unconscious she was quiet and her pulse fell from 200 to 140. An ether and chloroform mixture was the anesthetic. The operation was without incident, the right lobe and isthmus were removed and the patient recovered completely from the anesthetic and recognized her friends.

Result.—Towards evening she became excited, the pulse uncountable, respiration difficult, and the temperature rose to 104 F. She became quite maniacal and then subsided into a stupor and died during the night. Examination of the removed lobe showed some hyperplasia of the gland and it was found that the parathyroid had also been removed, and on examination was found to be quite normal.

Case 13.—Miss D., aged 23, for some years had had an enlargement of the thyroid which was soft and vascular.

History.—She has had frequent attacks of palpitation, tachycardia and excessive nervousness, which made her life miserable. She could do nothing and was getting worse. She had lost flesh. There was no exophthalmos and no tremors, although Graefe's sign was present.

Operation.—Dec. 2, 1898, the right half of the thyroid and the isthmus were removed. She had some symptoms of thyroidism after operation and perspired most profusely for some days.

Result.—At first there was no improvement but a year afterwards the patient said she was better than she had been for years and that the left half of the gland had diminished considerably. It was a colloid goiter with hyperplasia.

Case 14.—M. McL., aged 19,

History.—For two years she had noticed enlargement of the neck and latterly had been very nervous, breathless, and had suffered from palpitation; the eyes also had become prominent.

Examination.—A moderate enlargement of the thyroid was seen more on the left side; it was soft and vascular. The patient was excessively nervous, had a moderate degree of exophthalmos, and some breathlessness; pulse ranged 110 to 120.

Operation.—June 17, 1895, the left lobe and isthmus were removed. The left lobe contained an adenomatous growth.

Result.—The patient recovered well from the operation and left the hospital on the tenth day. She was much improved, pulse had come down below 100, and the nervousness was less. I heard of her some months after and she reported that she was quite well, had no tachycardia, and was much less nervous, but the exophthalmos still persisted.

[These notes were taken from my private operation book and from a short account on the back of a photograph. The complete hospital case record had been borrowed and never returned, and could not be found.]

These fourteen patients are all on whom I have operated with sufficient severity of symptoms to call the condition Graves' disease. Many patients have been operated on who had difficulty of breathing, rapid pulse, and some with a considerable degree of nervousness, but, although there were some of the symptoms of Graves' disease, yet they were not severe enough to be classed as exophthalmic goiter. Of the 14 patients operated on twelve patients have been benefited by operation, one has relapsed and one has been lost sight of; the deaths have been two, both in very advanced cases. The next three cases I mention shortly are patients who have been operated on by colleagues in the hospital, who have kindly consented to allow me to make use of them.

Case 15.—C. G., aged 19, had had gradual enlargement of the thyroid for five years.

History.—She had lost weight, was excessively nervous, had frequent attacks of palpitation, pulse 140, tremors, and marked exophthalmos.

Examination.—She had enlargement of the heart, a systolic murmur at the apex, and an accentuated second pulmonic sound. The left side of the thyroid was larger than the right, and the whole gland was much enlarged, soft and pulsating, except on the right side where the enlargement was apparently cystic.

Operation.—January, 1897, the patient was operated on; she lost considerable blood and never recovered consciousness after the operation. The autopsy showed a greatly enlarged thymus and excessive enlargement of both suprarenals.

Case 16.—E. B., aged 14, had been excessively nervous for two years and had had profuse sweats.

History.—For six months the voice had been affected and she had had difficulty in swallowing and excessive restlessness and periods of mental depression. Although there has been slight enlargement of the thyroid for two years, it had increased greatly in size during the past three months. Pulse ranged from 120 to 130. Tremors were well marked and there was great dyspnea on exertion; she had marked exophthalmos.

Operation.—The right half of the thyroid was removed in November, 1904, under local anesthesia, and the patient did well.

Result.—When last heard of some months after operation she had improved greatly and was much less nervous, and the pulse was 80 to 100.

Case 17.—Mrs. G., aged 33, had noticed increasing enlargement of the thyroid for the past sixteen months, and especially during the last three months.

Examination.—She had well-marked exophthalmos, tachycardia (pulse 120), tremors, great nervousness and excitability. Both lobes of the thyroid were moderately enlarged, the right being more prominent; the gland was firm, elastic, not very vascular, and of uniform consistence.

Operation.—In February, 1905, excision of the right lobe was performed under cocain and ether and the patient rapidly recovered, going out in eight days, with much better pulse (under 100), and not nearly so nervous. In this case there was very little colloid, there was hyperplasia of the gland with very small alveoli.

In most cases hyperplasia of the gland was found, in some the colloid matter was much more abundant than in others; in some the vesicles were smaller, and in others there was the folding in of the epithelium as described by MacCallum. I have not given the description of the microscopic sections, but have been content to make a diagnosis from the clinical symptoms which are complex. I do not yet believe that we can always tell by microscopic examination whether or not the condition is one of Graves' disease, for in many cases in which there were no symptoms, such as tachycardia, nervousness, etc., well-marked hyperplasia of the gland was found.

This being a surgical paper, I have not mentioned the medical treatment. The cases I have related had all been treated medically before being sent to me. Of the serum treatment I have no experience nor have I seen cases treated in this way, though I have heard that good results have been obtained in many instances.

DISCUSSION.

ON PAPERS OF DRS. ROGERS, BEEBE AND SHEPHERD.

Dr. L. W. Bacon, Jr., New Haven, Conn., is convinced that a little more careful analysis of the symptoms presented would enable the surgeon to elect among several possible surgical procedures the one best suited for the particular patient. In cases of what may be called the "sympathetic type," for instance, where on account of such symptoms as a unilateral exophthalmos it is difficult to ascribe the symptoms to hyperthyroidism or to any other form of a general intoxication, it is very reasonable to consider the possible advantages of the so-called sympathectomy over thyroidectomy. There is another class of cases in which the irregularity of the symptoms, and the extreme predominance of one symptom over another indicates perversion rather than mere excess of thyroid function; in these cases thyroidectomy is little likely to do good. In some of these cases there is a concomitant localized myxedema, and here Dr. Bacon regards thyroidectomy as distinctly contraindicated. When, as in some cases, the administration of thyroid extract is followed by an amelioration of the symptoms, this is an indication of perverted, rather than of excessive thyroid function, and in such cases thyroidectomy should be recommended with great caution.

The general conclusion Dr. Bacon has reached in the matter is that the more typical the case of exophthalmic goiter the more clear is the indication for thyroidectomy. Atypical cases may demand some other operation, or may, perhaps, be best treated by non-surgical means. Care should always be observed in advising any kind of an operation in these cases, and if on testing the case with thyroid extract it is found that this produces an amelioration of the symptoms, and likewise, in that certain small percentage of cases where the disease apparently is not due to a distinct intoxication, abstension from thyroidectomy should be the rule. For, however logical a means this operation may offer for the reduction of an excessive secretion, for the correction of a function perverted in quality its logic is less evident, and for the cure of those patients who may present many of the symptoms of exophthalmic goiter, but whose troubles are dependent on organic changes in the central nervous system, thyroidectomy is probably worse than useless. The line of progress in the surgical treatment of exophthalmic goiter will lie in the more careful analysis of the cases.

Dr. H. M. S. Dawbarn, New York, believes that in view of the brilliant results obtained by Drs. Rogers and Beebe, surgeons are not justified in attempting any surgical intervention without first trying the serum treatment. He has used the ligation method instead of partial thyroidectomy in four instances, with the greatest benefit. The object of the removal of a portion of the thyroid is to get rid of the excess of thyroidin thrown out in excess by the gland. If the same results can be accomplished by shrinkage of the thyroid gland, simply through tying off all the named thyroid arteries, two great benefits are attained. First, there is avoided the risk of removing a part of the gland, with its occasional consequent rise of temperature and sudden death; the ligation method being, on the other hand, practically devoid of mortality. Second, since the majority of these cases occur in women, the resulting appearance is important to consider. The removal of the thyroid on one side leaves a depression, whereas there continues a bulging on the other side, there thus being a lack of symmetry and never a very grateful patient. By the method Dr. Dawbarn is advocating, there is nothing worse than a delicate linear scar running down the neck on each side. Inasmuch as there is no case on record in which ligation of both the superior and inferior thyroid arteries, and also any other artery that may be found going to the gland, has been followed by gangrene of the gland, there can be no objection to tying all of these vessels. There will remain anomalous vessels enough for nourishment. Dr. Dawbarn ties them on both sides at the same sitting and, in his experience, they have been so very large that they can be found without the least difficulty. The resulting deformity is almost *nil*. That being the case, it seems that inasmuch as in each instance there has been very rapid and permanent shrinkage of the thyroid, and since it is so very safe a plan and does not necessitate handling of the gland, it is the thing to try rather than any more severe and mutilating method.

Dr. A. J. Ochsner, Chicago, said that there are four distinct dangers connected with anesthesia in operation for exophthalmic goiter. 1. There is the danger of the anesthetic itself. These patients, unless anesthetized with great care, are very liable to get into trouble. If the anesthetist is at all careless the patient may be so thoroughly asleep that it will be difficult or impossible to arouse him. 2. There is the danger of producing a toxemia incident to the possibility of violently handling the enlarged gland while the patient is asleep. He can not at that time object to any violent treatment, and it is possible to squeeze the thyroid juices into the circulation. The result is high temperature and sometimes a fatal issue. 3. There is the danger of injuring the recurrent laryngeal nerve, which does not have to be reckoned with when the patient is awake, because the moment it is picked up the patient becomes hoarse. 4. And, finally, there is the danger of infection through the breath of the patient, the patient breathing and infecting his own thyroid through his breath.

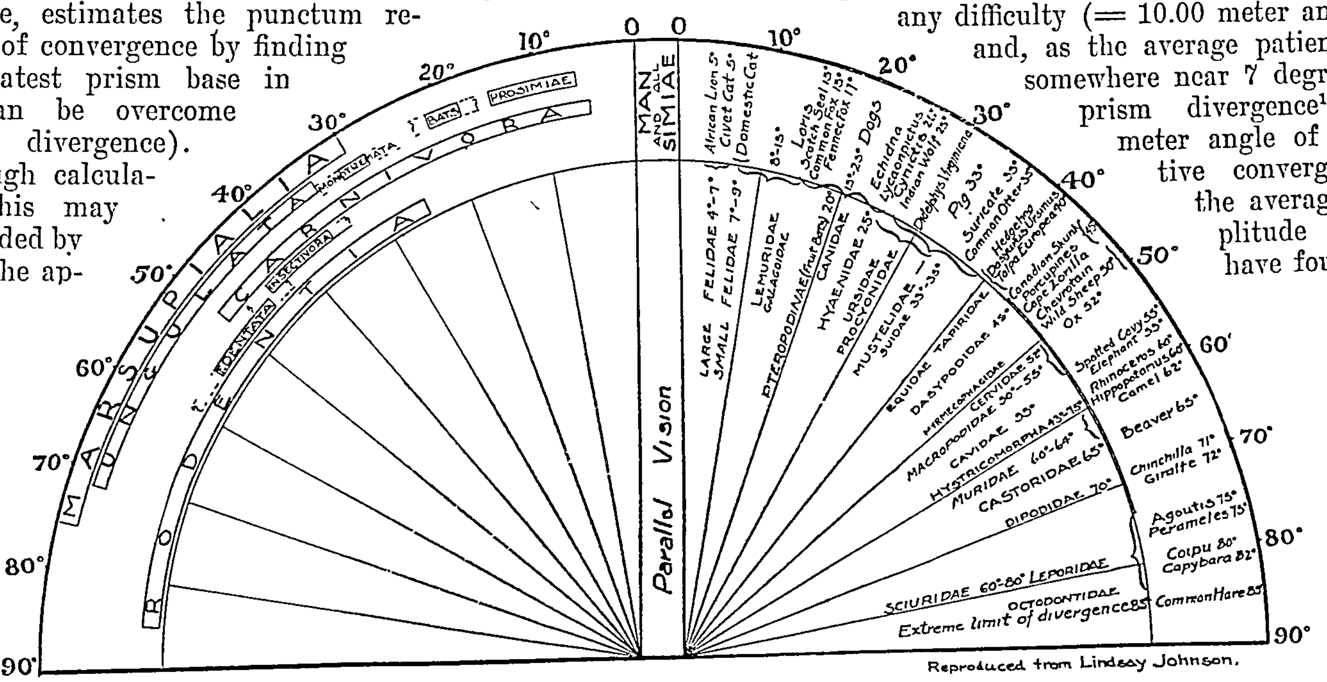
Following a suggestion made by Dr. Crile some years ago Dr. Ochsner avoids all these troubles by thoroughly anesthetizing the patient with ether while he is in the horizontal position, then covering the mouth and nose with about ten thicknesses of aseptic gauze, then elevating the head of the patient by placing him in the inverted Trendelenburg position and utilizing the resulting anemia, in place of the anesthetic, for the remainder of the operation. It is always possible to complete the operation without giving any more of the anesthetic, and by the time that the recurrent laryngeal nerve is reached in the course of the operation the patient will be partly out of the anesthesia and able to speak so that he can warn the operator of that danger, which can also be avoided in that way. In fact, so can all the dangers that depend on the anesthetic. and there is the advantage of having the patient quiet so that the operation can be completed very rapidly.

The operation which Dr. Ochsner has performed on many patients has been the following: He removes the middle and larger lobe and ligates the inferior thyroid artery and vein on both sides, which reduces the size of the thyroid on the opposite side, so that no deformity results. One case was operated on as long as fourteen years ago. The patient is still in excellent condition. Dr. Oschner thinks that the serum treatment is still in the experimental stage. If, however, it proves to be useful, then the operative treatment must be reserved for those cases in which the serum proves useless. At present, the operation, if performed in this way, is certainly a relatively safe and satisfactory procedure.

Dr. J. Shelton Horsley, Richmond, Va., stated that the pathology of exophthalmic goiter seems to be accepted as being due to the thyroid gland itself and not to a disease of the nervous system. This is proved by several things. First, by the fact that operations attacking the thyroid itself seem to be productive of the best results. Second, by the magnificent work of Drs. Rogers and Beebe who have elaborated this serum which acts only on the thyroid gland and employed it

In 17 persons who had parallel ocular axes during life, he found divergence postmortem. He concludes, therefore, that even in civilized man there is a tendency toward divergence which is overcome by fixed innervation. This fixed innervation is what Maddox[6] calls tonic or initial convergence.[7]

In Figure 3 he represents convergence as composed of three elements: the initial or tonic element, the accommodative element, and the reflex element, although exception might be taken to the latter element. It is simpler to resolve convergence into two elements, namely, initial or tonic convergence (the phylogenetic convergence of Pohlmann) and accommodative convergence (Fig. 4). This, however, is the academic phase of the matter. Landolt approaches the subject of convergence in a much more practical fashion and shows how deeply he feels that it is a problem sufficiently often encountered in the flesh to merit our earnest study. He prefers to measure the amplitude of convergence,[8] because of his conviction that that is the key to many otherwise puzzling anomalies of convergence. He, therefore, estimates the punctum remotum of convergence by finding the greatest prism base in that can be overcome (prism divergence). For rough calculation, this may be divided by 7 and the approximate degree of negative convergence (or divergence) in meter angles thus obtained. For instance, if prism divergence be 7, there is one meter angle of negative convergence. For estimating the postive convergence, prisms are not of sufficient value, because of the varying quality of convergence so estimated. His preference is for the ophthalmodynamometer (of his own contrivance). For this purpose I have for three years employed what seems to me a much simpler device. Using the one-candle electric light of the DeZeng electric ophthalmoscope, I half-darken the room and then, starting at 15 inches from the face, have the patient watch the light attentively as it is carried in the median line toward the eyes. At about 10 inches from the eyes the corneal images from the electric light become plainly visible to the surgeon, and it is then easy to watch these images as the light is carried toward the root of the patient's nose until one or the other of the corneal images comes to a standstill. This is the near point of convergence, and one can readily calculate the number of meter angles of positive convergence at the patient's disposal. For instance, if one of the corneal images comes to a standstill at 4 inches, there are 10 meter angles of positive convergence; if at 5 inches, there are 8 meter angles; if at 3 inches, there are 13 meter angles. The test as thus applied is objective, while Landolt's procedure is subjective and open to all the disadvantages of every subjective test. This test is applied in about 5 seconds, as a rule.[9] The amplitude of convergence is, hence, the sum of the positive and negative convergence. Thus if there be 9 degrees of prism divergence (1.28 meter angles of negative convergence), and the corneal images come to a standstill at 4 inches (10 meter angles of positive convergence), the total amplitude = 1.28 + 10.00 = 11.28 meter angles of convergence.



Reproduced from Lindsay Johnson.

The Natural Orders are represented on the left-hand quadrant, the Families, Genera and Species on the right.

Figure 2.

By the above test I have found that the average patient converges to 4 inches (10 centimeters) without any difficulty (= 10.00 meter angles), and, as the average patient has somewhere near 7 degrees of prism divergence[10] (1 meter angle of negative convergence), the average amplitude as I have found it in my office is about 11 meter angles. Landolt has found 10.50 as his average. He has further shown[11] that of the total 10.50 to 11.00 meter angles the reserve ought to be about twice as great as the convergence required by the work, and that is about what occurs in the average individual. Most work is done at about 13 inches from the eyes, that is, it requires about 3 meter angles of convergence, and this leaves from 6 to 7 meter angles of reserve, or a trifle more than twice as much as the ordinary amount used. If there be much departure from this relation, there is almost sure to be some discomfort in the use of the eyes at the occupation distance. As these two tests—estimation of the prism divergence and estimation of the convergence near point—can be accurately executed in from 3 to 4 minutes, there can be little excuse for omitting them in any patient with exophoria who has not been made comfortable by the use of a nonprismatic correction only. Indeed, I believe it wise and valuable to make them in all cases of exophoria before dismissing the patients to try the effect of their proper correction.

[9] It is also worth while in pursuing this test to approach the light from the right and left side as suggested by Duane.

[10] In 60 consecutive cases of exophoria it was found to be 7.5 degrees.

[11] Arch. Opht., March, 1886.

ANALYSIS OF FOUR HUNDRED AND FORTY-ONE CASES OF EXOPHORIA.

In the analysis of the following 441 cases, these facts are to be borne in mind:

1. All of the cases occurred in private practice.

2. Only cases presenting stereoscopic vision have been included in the analysis (hence exotropia is excluded).

3. Proper correcting lenses were prescribed by me and tried thoroughly before proceeding to the treatment of the exophoria as an intrinsic condition, or the patients had been recently refracted by a trustworthy ophthalmologist.

4. No selection of cases for these statistics has been made. They have been taken consecutively and include all the cases of exophoria I have seen in private practice.

5. Refraction with a mydriatic was done in practically every patient under 45 years of age when I did the refraction myself. Over that age the refraction was done without a mydriatic.

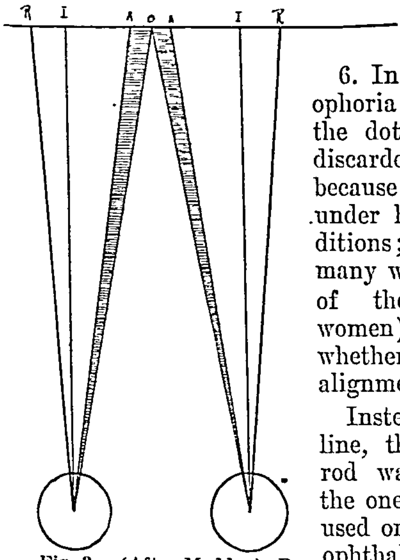

Fig. 3.—(After Maddox). R, Punctum remotum. R. I., initial convergence. I A, accommodative convergence. A O, reflex convergence.

6. In testing for exophoria at the near point, the dot and line test was discarded entirely, first, because it places the eyes under highly artificial conditions; second, because many women (and the bulk of these patients were women) can not tell whether objects are in alignment or not.

Instead of the dot and line, the Maddox multiple rod was used, along with the one-candle electric lamp used on the DeZeng electric ophthalmoscope (described above in connection with the convergence near-point test). This little light the patient holds at the ordinary occupation distance (about 13 inches), and by means of the multiple Maddox rod great delicacy is secured, one-fourth of a degree of error being easily thus revealed. In presbyopes the reading correction should be used when this test is applied or the observer will be led into error. Schild's, Baer's or any other development of the simple apparatus I have described may be used, but for six years I have found the simple one-candle electric light and the Maddox rod satisfactory in every way.

7. In testing prism divergence (abduction) and prism convergence (adduction) separate prisms were used, the prism divergence being always estimated first. In obscure cases the following 7 points were considered essential to a proper study of the case: (a) The exophoria for infinity (or distance); determined by both the cover test and the multiple Maddox rod.[12] (b) The hyperphoria for infinity. (c) The prism divergence (abduction). (d) The prism convergence (adduction). (e) The exophoria for 13 inches (33 centimeters). (f) The hyperphoria for 13 inches (33 centimeters). (g) The convergence near point.

These seven maneuvers may be accurately gone through in from 6 to 8 minutes and are well worth systematic employment in every obscure case of exophoria in which symptoms persist in spite of the best refraction.

Age.—The frequency of exophoria in the various decades of life is given in Table 1, which shows plainly the influence of age in its production. The occurrence of less than one-tenth of all the cases before the twentieth year is a significant fact. Weiss[13] calls attention to the outward swing of the orbits (and along with them their long axes) after puberty. Duane[14] notes those cases in which divergence has developed as a result of the gradual divergence of the orbits taking place during the period of growth in children and youth. "This divergence, by altering the angle of insertion of the tendons and the amount of tendon in contact with the eyeball (contact arc), increases very greatly the power of the externus and diminishes that of the internus, and in itself is quite sufficient to account for the development of divergent strabismus." If it will give rise to so pronounced a deviation as divergent strabismus, it may well be asked: How much more easily may it give rise to a latent deviation or exophoria?

Sex.—Of the whole number here reported 161 patients were males and 280 females, or a proportion of 6 to 11. That is to say, there were almost twice as many women as men presenting exophoria. These figures accord very well with those furnished by analyses of large numbers of refraction cases (say 1,000 to 2,000)[15] which show that about twice as many women as men apply for refraction in private practice. Women's nervous systems are admittedly less resistant than men's, and it is also probable that women employ their eyes more at the occupation distance than do men. Neurasthenia, too, for many reasons, is much more likely to occur in women than in men. Yet examination of 33 cases of exophoria of the neurasthenic type occuring in this whole series were practically equally divided between the two sexes, 15 of the patients being men and 18 women. It is altogether probable that if the figures could be so extended as to include an equal number of males and females exophoria would be found to occur as often in 1,000 men as in 1,000 women.

---

[12] The cover test seems to me one of the most valuable tests at the ophthalmologist's service if applied as follows: The patient is made to survey some small object on a homogeneous background (like a blank wall or a small point of light looked at in a mirror across the room; by reflecting the light in this way a good distance can be obtained for the test). With the patient's gaze fixed on the fixation object, a card is carried in front of the eyes from right to left, covering first one eye and then the other. This maneuver should be repeated from 10 to 15 times to break in *on* the fusion impulse as much as possible, great care being taken that at no time, as the card is being moved, both eyes get a simultaneous view of the object else the point of the test is lost. By attentive observation, the eyes will be seen to give a slight jump in or outward as they are alternately uncovered, unless there be lateral balance or less than 1 degree of error. This test is wholly an objective one, and its objectivity and accuracy give it great value. If it is desired to make the test subjective (by asking the patient after a few movements with the card whether the fixation object appears to jump from side to side as the card is shifted), it is very readily done. So carried out, it becomes the parallax test, and is of the greatest delicacy, one-fourth of a degree of deviation being easily possible of detection in intelligent patients.

Stenographers	15	Salespeople	7
Professional people	92	Storekeepers	8
Outdoor workers	7	Housewives	120
Laborers	3		
Mechanics	10	Total	441

Occupation.—Table 2 has to do with the occupation of the 441 exophorics. These workers may be arranged in three groups as follows:

1. Those who use their eyes at the occupation distance most of the day.

2. Those who use their eyes little or not at all at the occupation distance.

3. Those whose days are fairly well divided between general work and near work, e. g., housewives.

Thus the students, accountants, desk workers, stenographers, professional people, needle workers (including loomworkers) show a total of 272; the outdoor workers, laborers, mechanics, farmers, merchants, collectors, salesmen, shopkeepers, etc., show a total of 49, while the housewives number 120. In other words, practically two-thirds of the whole number of exophorics were what might be called near workers. I am inclined to attach some importance to these particular figures; for if one be engaged more or less all day in near work, even though they wear a perfect correction, they are very likely to have some symptoms of discomfort at their work if they present exophoria for infinity; in my experience exophoria at infinity generally means deficiency either in the amount of convergence or in the faculty of using it.

TABLE 3.

11	1		

The degree of exophoria occurring in these 441 cases is shown in Table 3. As in hypermetropia, so in exophoria the smaller degrees of error predominate; the parallel is further borne out by the fact that, as a rule, the smaller deviations carry with them the most marked symptoms, and for the same reason, that they are overcome all day long. Of the whole series of 441 cases, 309, or 70 per cent., were of 3 degrees and under. Only 32 times, or in 41 per cent., did the deviation amount to 10 degrees or more. In 7 cases it reached 15 degrees, in 3 cases 18 degrees, in one case 20 degrees, and in one other 25 degrees. Naturally, these last few were practically instances of suppressed (or overcome) divergent strabismus (anatomic exophoria), which will be alluded to later.

TABLE 4.

In 441 cases of exophoria there was associated:

H + ah in	176 cases.

Refractive Status.—We next come to the relation that exophoria bears to the various states of refraction as set forth in Table 4. Despite the fact that exophoria has been looked on by many authorities as a passive condition, it will be seen by reference to the table under consideration that this belief is no longer tenable. That a certain small percentage does represent a passive or under-action phenomenon (in reality an accommodative exophoria) is a well-established fact. But Table 4 shows at a glance that in 441 cases this anomaly was associated with hypermetropia or its allied refractive conditions (H + ah-ah-ahm + H) 313 times, or in 72 per cent. of the cases. And inasmuch as all hypermetropic conditions call for excessive accommodation (hence associated excessive convergence impulse); we may be sure that a certain portion of latent exophoria is masked in such cases by the attempt on the part of the patient to overcome the hypermetropia. Herein lies the unwisdom of anything like a full correction of the spherical element in the hypermetropia associated with exophoria.

Myopia and its allied condition (Am, M + Am, Amh) were present in 89 of the 433 cases (20.5 per cent.) and it is probable that a certain proportion of these were accommodative exophorias.

There remain to be considered 31 (or 7.5 per cent.) cases of antimetropia (the so-called anisometropia) in which it will be later shown that the average degree of exophoria was higher than in any other refractive condition.

Subdivisions of Exophoria.—The term exophoria, while of great clinical convenience, is not altogether sufficient to the purpose for which it is employed, in that it gives no clew to whether convergence be deficient, divergence excessive, or the two conditions coexistent. So that, for purposes of statistical study and better understanding of the cases, it becomes necessary further to subdivide a proportion of the series herein offered into:

1. Exophoria with normal divergence and deficient convergence.

2. Exophoria with divergence excess.

3. Exophoria with convergence and divergence both deficient.

These may be, for greater convenience, put down as: (a) Asthenic exophoria (Savage), true convergence insufficiency; (b) sthenic exophoria (Savage), anatomic exophoria; (c) neurasthenic exophoria.

In the series of cases here offered there were 200 in which there was only partial or no relief to the patients' symptoms afforded by correcting lenses alone. Of this latter number there were 121 in which the prism convergence and the prism divergence were estimated in the further study of the cases. Arranging these 121 according as they showed subnormal, normal or excessive divergence, we find the following:

Thirty-five times, divergence and convergence were subnormal; 23 times, divergence was normal and convergence was subnormal; 63 times, divergence was excessive and convergence subnormal. Or to tabulate them more in detail:

TABLE 5.

Conditions.	No. of Times Found.	Average Exophoria for Infinity.	Average Prism Convergence.	Average Prism Divergence.
Neurasthenic exophoria	35	1.80°	9°	5.5°
Asthenic exophoria. . .	23	2.25°	11°	7°
Sthenic exophoria.	63	3.00°	14°	8°

This table shows that over 60 of the class so studied proved to be sthenic or intrinsic exophorias (divergence excess of Duane), a proportion that, it is thought, will hold for the whole series. It further shows that the average exophoria increases as the prism divergence increases (as would naturally be expected). Finally, it sustains Seabrook's claim that exophoria for infinity almost invariably means subnormal convergence, whether the exophoria is asthenic, sthenic or neurasthenic. The influence of hyperphoria in reducing both prism divergence and prism convergence is well known, and no case of exophoria should be put down as neurasthenic until hyperphoria of three-quarters of a degree or more has been excluded. Table 6 was drawn up for the purpose of comparing at every point 6 cases each of neurasthenic, asthenic and sthenic exophoria.

Several interesting practical points are brought out by this table. It is commonly accepted that from 10.50 to 11.00 meter angles of convergence amplitude are sufficient for comfortable work at the near point; and yet in Cases 5 and 6 of Group 1 in Table 6 there was exophoria of 8 degrees for the reading distance in both cases, with a convergence amplitude in one case of 12.00 m.a. and in the other 13.85 m.a. In Cases 1 and 4 of Group 2, there was exophoria of 12 and 10 degrees, respectively for the reading distance, with a convergence amplitude of 21.00 m.a. (!) in each case. It will be readily seen that, while all 4 of these patients possessed convergence amplitude much in excess of what is generally considered quite sufficient, they had all learned the trick of using the power that was potential in their adducting muscles all the time.

Contrast with these Patient 5 of Group 2, who presented an exophoria of 2 degrees for both distance and near work, in spite of the fact that her convergence amplitude was but 8.50 m.a. Here was a patient who, though her convergence amplitude was not all that it should be, yet held her adductors up to their work almost perfectly, for she was almost without symptoms. Too, she was one of those individuals who have themselves well in hand and accomplish all things well; moreover, her physical condition was superb.

* Cases with subnormal prism divergence.
† Cases with normal prism divergence (= 7 degrees).
** Cases with excessive prism divergence.

The following 5 cases illustrate well the value of estimating both the exophoria for the near point and the amplitude of convergence—for if the exophoria for the near point be much greater than that for infinity and the convergence amplitude be normal—the necessity for convergence training, with prisms or otherwise, is apparent. Such patients need to be shown how to use a faculty they already possess. On the other hand, when exophoria for the distance shows no increase when estimated for the near point, though the convergence amplitude be normal or even above normal, not so much need be expected from further training of a faculty the patient already knows how to use and is probably drawing on heavily.

A word as to the proportional relation between prism divergence and prism convergence. In 1895, Risley[16] stated his belief that muscular asthenopia frequently proceeded from disturbance between the relation of adduction to abduction which should be as 3 to 1. This was based on results obtained with the rotary prism. Some time earlier Noyes had spoken of 5 or 6 to 1 as the normal relation. Following Risley, Bannister[17] went over 100 U. S. Army recruits and, using separate prisms from the trial case, came to the conclusion that "there exists in healthy eyes no positive definite relation between prism convergence and prism divergence for distance, and that it is not correct to claim that such eyes should, without practice with prisms, show at 6 meters a ratio between these functions of 3 to 1 or 6 to 1 in favor of convergence, not permitting abduction to fall below 6."

Naturally, much depends on the way in which the tests are applied. Convergence is a variable elastic quantity. Prism divergence is a fairly constant one. It would seem wise, therefore, first to test the prism divergence, gently leading the patient along by having him close his eyes from time to time and open them suddenly, with the purpose of arriving at his greatest possible prism divergence, then closing and resting the eyes for a few minutes before estimating the prism convergence. This was the method employed in the subjoined series of 121 exophorics in whom it was found that: prism divergence was in excess 12 times; prism divergence and prism convergence were equal 10 times; the relation of prism convergence to prism divergence was as 1½ to 1, 30 times; as 2 to 1, 41 times; as 2½ to 1, 19 times; as 3 to 1, 7 times; as 4 to 1, twice.

Bannister's figures appear to be very good ones to work from, as they are based on methods largely in use in ophthalmic offices the country over. As compared with them, it will be seen that in exophoria the relation of prism divergence and prism convergence varies in so confusing a manner as to attach little value to their relative behavior. Estimation of the near point exophoria and convergence near point are more essential. Necessarily the amount of prism convergence in a case of exophoria is always of interest; for instance, if a patient's distance vision begins to blur when a 6, 8 or 10 degree prism is placed base out before the eyes, the inference that their prism convergence is defective and that they have not learned to dissociate their accommodation and convergence is entirely justifiable.

---

[16] Univ. Med. Mag., 1895.
[17] Annals of Ophth., 1898.

In Table 7 the average exophoria in the various states of refraction is shown and we here find food for thought:

TABLE 7.

		Average exophoria.
H + Ah and allied conditions.....	319 cases.	2.5 degrees.
M + Am and allied conditions....	90 cases.	3 degrees.
Ahm	17 cases.	3 degrees.
Amh	17 cases.	4 degrees.
Antimetropia	31 cases.	5 degrees.

In H + Ah as it commonly occurs, stereoscopic vision is usually very little, if any, hindered, and the average exophoria associated with it is but 2.5 degrees. In antimetropia (the so-called anisometropia) where dioptric inequality between the two eyes ofttimes interposes a weighty hindrance to smooth, easy stereoscopic vision, the average exophoria rises to 5 degrees. In other words, when there is sufficient obstacle to the performance of *stereoscopic vision, the eyes tend toward the position of* anatomic rest, which is a heritage to us from our forebears for countless generations. Exophoria thus reveals itself as a reversion to a lower type and may justifiably be considered an atavistic phenomenon, as claimed by Lindsay Johnson, Pohlmann, LeConte, Jackson and others. The data here given lend firm statistical support to that contention.

As to symptoms, 200 of the 441 cases here catalogued presented symptoms of muscular asthenopia persisting after careful correction of their refraction. Of these two hundred, 173 exhibited headache, the frontal type predominating in 102, the occipital in 60, the temporal in 11; while 140 gave testimony as to more or less vertigo, especially after near work. Ocular fatigue and ache were present in 153, ocular tenderness in 98, conjunctival irritation was complained of in 121, low-grade photophobia in 130. Nausea seemed fairly well related to the exophoria 72 times; and drowsiness after near work was almost invariable, as was also picture-gallery and after-shopping fatigue. Gastric reflexes seemed etiologically related to the exophoria in 23 cases in an unmistakable way. By gastric reflex is meant the nameless vacant sensation in the epigastric region so perfectly described by DeQuincey in his "Confessions." That a certain proportion of exophorics (who overcome their exophoria) have this reflex is indisputable. Two cases presented intractable superior dental neuralgia (with teeth in the most perfect condition) that yielded to prisms, bases in, for permanent use. Another case exhibited the complete picture of acute glaucoma that subsided within three days after the incorporation of prisms, bases in, in distance correction.

Treatment.—The treatment of exophoria calls for about as nice discrimination as any problem in medical practice.

First of value, I would place right living, hydrotherapy and abundant sleep; second, the most painstaking refraction; third, convergence training. This may be of various kinds, but I have resorted mainly to two kinds, namely, converging exercises on a pencil from arm's length in toward the root of the nose until the convergence near point is reached and the patient sees double. This was invariably prescribed to every exophoria. Pencil converging exercises to the left and right (as suggested by Duane) was of service in a few cases.

The second element in convergence training is by means of prisms, bases out, according to the method popularized by Gould as "weighting the convergence stimulus." The patient is given a pair of 5-degree prisms in a frame with which he walks toward a candle flame, placed at the far side of the room. The prisms are raised as he goes toward the light. As soon as he reaches it, the prisms are dropped before the eyes and he backs away from the light, gazing steadily at it all the time. Should the light be seen double, the patient immediately retraces his steps and again backs away from the light until he goes the entire length of the room, holding the candle light single. This is done from ten to fifteen times, two or three times daily. After a week, 10-degree prisms are ordered to be used in the same way; in another week or two, 15 degrees or 20 degrees *according as the patient rapidly or slowly learns* the trick of dissociating his accommodation and convergence. This method is of value in all exophorics.

Prism exercises were resorted to in this manner in 147 of the 200 cases as the sole optical treatment aside from the wearing of a proper correction; in 26 more the exercises were employed in connection with the use of prisms, bases in, in the patient's distance correction; and in 27 more in connection with the use of prisms, bases in, in the patient's reading glasses.

4. In Prisms, Bases In, for Permanent Use.—The use of prisms, bases in, to be incorporated in the patient's distance correction, has been deprecated by various high authorities. Their chief (and almost unanimous) contention has been that the exophoria for infinity increases under the use of such prisms. That this is true, within certain limits, must be admitted; and yet in anatomic exophoria,[18] when proper correction of the ametropia has failed to relieve, and attempts at training the convergence have been poorly borne, the trial of prisms, bases in, in an extra or hook-front experimentally seems to me entirely justifiable. In cases so selected, it will be found that when convergence has been made somewhat easier to the patient by the use of rest prisms, the convergence may then be trained to a very considerable point, and the convergence for infinity thus kept from increasing. This was my experience in 17 out of 42 cases in which prisms, bases in,[19] were ordered for constant use. It is no more surprising that the exophoria should increase in these cases of anatomic exophoria than that a patient should gradually manifest more and more of a latent hypermetropia as plus lenses are skillfully crowded on his eyes. And I believe there are few cases of anatomic exophoria (due to orbital peculiarities, insertional anomalies, etc.) in which there is not a considerable element of latent exophoria unrecognizable with the Maddox rod because of the overwhelming fusion impulse in such individuals. For such patients I know of no test comparable to the cover test if employed as previously described. It is as wrong to order prisms, bases in, for permanent use without soon after training the convergence to the highest possible point as it would be to rest an inflamed joint and then not exercise it afterward. Many of these patients have a splendidly developed convergence, but it is because of their excessive use of it all day long in overcoming their exophoria that they have their symptoms.

A class of patients for whom convergence training is even more plainly indicated are the exophorics who present but 1 or 2 degrees of deviation for infinity with anywhere from 10 to 15 degrees' deviation at the reading distance (prism divergence being normal). These patients respond finely to convergence training as a rule. There is, however, a small outlying percentage in whom it will be found necessary to supplement convergence with prisms, bases in, in their reading glasses only (these patients are mainly presbyopes) before they become entirely comfortable in near work. In 45 patients for whom prisms, bases in (or decentered lenses), were used, there were ordered prisms correcting one-quarter of the infinity exophoria in five cases; one-half of the infinity exophoria in eight cases; two-thirds of the infinity exophoria in ten cases; the full amount of the infinity exophoria in ten cases; more than the full amount of the infinity exophoria in twelve cases, with uniformly good results.

---

[18] By this is meant exophoria with highly excessive prism divergence and defective temporal arc rotation. (The "Divergence Excess" of Duane; or the "Intrinsic Exophoria" of Savage).

[19] Minus prisms Maddox prefers to call them.

There may be room for doubt as to the wisdom of ordering prisms for constant use, but one need not hesitate to order prisms, bases in, for use in reading glasses only if the divergence for the near point exceeds 10 degrees. From one-third to one-half of the deviation for the near point will usually be gratefully accepted.

OPERATION.

When it comes to the question of operation in exophoria (after all the preceding measures have failed to relieve) there is the widest variation of views among the writers on this subject.

When exercise of the function of convergence has failed Landolt[8] is devoted to advancements. In Hansell's experience[20] advancement will often permanently cure. Savage and Thomas[21] both indorse muscle shortening as the operation of election when other means have not relieved the patient. Posey[22] did DeWecker's capsular advancement in 33 cases of pronounced exophoria, and states that, although after a lapse of two years there seemed but little objective gain, the improvement in the symptoms was marked and would seem to justify the operation. W. R. Parker,[23] if "driven to operation" (and this ought to be the stand taken by every ophthalmic surgeon—he should feel driven to operation), does tenotomy or advancement according to the indications.

In the series here discussed (441 cases) operation was done seven times, and in each instance tenotomy was resorted to. In three cases, the amount of exophoria operated for equaled 10 degrees, in one case 12 degrees, in one case 13 degrees, in one case 18 degrees, and in one case 20 degrees. In two cases in which both externi were equally and moderately divided at the one sitting, there was subsequent homonymous diplopia for three to four weeks, especially in the temporal periphery, but this eventually left the patients with vastly more useful eyes than they had ever had before. All these seven patients were markedly helped by the operation. In each one convergence training (begun from three to seven days after operation) was relied on to finish a cure. Theoretically, advancement is strongly indicated in exophoria, yet in the anatomic variety, with convergence decidedly insufficient and divergence more decidedly in excess, I can see no reason why tenotomy should not be done, first, because there seems no danger of nasty after-results (from five to six years after the tenotomy, such as we see in tenotomies for convergent squint); second, tenotomy is infinitely easier than advancement for these functional conditions and vastly easier of adjustment to the particular condition in each individual, whereas advancement is very much clumsier and more difficult of performance.

In spite of the feeling in some quarters that the stitch by means of which advancement is done is very simple and very easy, I feel disposed to continue doing tenotomies in the very few exophorics (slightly less than 2 per cent.) who need operative help.

CONCLUSIONS.

Finally, the following conclusions growing out of twelve years' earnest thought and work with exophoria are offered with all diffidence as to the result of that experience:

1. Exophoria, as a symptom-producing quantity, has come to the point where it must be viewed as an atavistic phenomenon—a reversion to a lower type—a stigma of degeneration, if some one wishes to insist on it. (I do not hesitate to use the latter designation, as I am myself an exophoric.)

2. All the advantages of binuocular stereoscopic vision are conditioned on convergence only.

3. Convergence as it is daily dealt with may be said to be composed mainly of two elements—the initial or tonic convergence and the accommodative convergence.

4. The amplitude of convergence ought to be always calculated.

5. The average patient has somewhere between 10 and 11 meter angles of convergence.

6. The reserve amount of convergence ought to be about twice as great as the convergence required by the work.

7. The cover test is the most reliable test for study of the position and behavior of the eyes when fixed on an object at twenty feet.

8. When converted into the parallax test much added delicacy is secured.

9. The Maddox rod and a small electric light are much superior, as a test for the muscle balance at the reading distance, to the vertical diplopia test.

10. Nine-tenths of all cases of exophoria will be encountered in individuals over 20 years of age.

11. The frequency of exophoria in the male and female is about equal.

12. Exophoria for infinity generally means deficiency either in the amount of convergence or in the faculty of using it.

13. Low degree exophorias are the most common and the most symptom producing.

14. The average degree of exophoria is least in H + Ah conditions, rises through the M + Am conditions, and is highest in antimetropia.

15. Exophoria assumes three principal forms; i. e., (a) asthenic exophoria (convergence insufficiency), (b) anatomic exophoria (sthenic exophoria), (c) neurasthenic exophoria.

16. About 50 per cent. of exophorias are of the sthenic or anatomic variety.

17. The test of the muscle balance at the reading distance is no measure of the total converging power of the patient and must be supplemented by tests for the convergence near point.

18. The prism convergence is only of relative value as a working indication.

19. The relation of 3 to 1 as between prism convergence and divergence will not nearly hold in exophoria.

20. The influence of hyperphoria in often reducing the power of both divergence and convergence is well

known, and no case of functional divergence should be put down as a pure exophoria until hyperphoria of three-quarters of a degree or more has been excluded.

21. In hyperexophoria the use of suitable vertical prisms, with convergence training, will frequently do away with all the patient's symptoms.

22. The symptoms of exophoria do not differ materially from those of other forms of eyestrain.

23. The treatment of exophoria should comprise (in the following order): (a) Right living; (b) careful refraction; (c) convergence training; (d) prisms (bases in) for infinity; (e) prisms (bases in) for the reading glasses only; (f) tenotomy or advancement.

1212 Spruce Street.

DISCUSSION.

DR. EDWARD JACKSON, Denver, in the main, and particularly in his conclusions as to treatment, agreed with Dr. Reber. These conclusions, and particularly the order of importance of the different therapeutic measures, he said, ought to be impressed and taught widely, viz., right living, careful refraction, convergence training, prisms, tenotomy or advancement. These are by no means of equal importance. Both in the number of cases to which it is applicable and in its importance in the cases to which it does apply the first stands far ahead. We can not by operation and training make up for the faulty nutrition of the nervous system. As to the amount of reserve convergence, most ophthalmologists who have carefully studied the accommodation have realized that the amount of accommodation that must be kept in reserve, for the comfort and health of the patient, varies greatly in different persons. It has seemed to Dr. Jackson that the proportion of convergence that could be used habitually varied even more widely, and in general that but a small part of the convergence should be used.

He agreed with Dr. Reber that exophoria becomes more common with increasing age, more particularly as regards near work. Inability to sustain convergence for near work he finds very common at the age of presbyopia. A great many patients are relieved quite as much by prisms, bases in, as they are by change of lens. For a good many years he has tested all refraction cases as to muscle balance with the Maddox rod test, and low degrees of exophoria are extremely common. He would not say that the low degrees are so likely to produce trouble as the high degrees. If we take the total number who develop asthenopia, probably more than one-half of them have quite low degrees. But the number of people who present that amount of exophoria is so much greater than those who present the higher degrees that the low degrees are evidently less likely to cause trouble.

DR. ALEXANDER DUANE, New York, referred to the following points in Dr. Reber's paper: First, as to the convergence near point, he thinks the distance usually given for this (four inches from the center of rotation of the eye) is too great. In his experience for extreme convergence in normal cases the point is not more than three inches from the center of rotation of the eye, or practically two inches from the root of the nose. He determined it very simply by using a very small white headed pin, which is carried in rapidly toward the eyes. The movement, when the convergence near point is reached, is determined (a) subjectively by the fact that the patient sees the pin double; (b) objectively by the fact that the physician can see one of the patient's eyes oscillate and diverge. It is important in this regard to note which eye diverges. In exotropia there is often a relative convergence near point, i. e., the point down to which the patient still makes the attempt to converge, although he may never actually succeed in converging on the object of fixation. It is an important matter to determine this relative near point, for a patient with a comparatively close relative near point affords a much better prognosis both for operation and for orthoptic treatment, than one who makes no attempt at convergence at all.

Second, in testing the exophoria for near he agrees with Dr. Reber that the dot and line (phorometer) test is not very satisfactory, but instead of using the Maddox rod for determining this he uses the cover test (measuring the deviation with prisms), and is sure that he gets trustworthy and precise results.

Third, he can not agree that exophoria for infinity almost invariably means subnormal convergence. In very many cases the presence of 10, 20 or even 30 degrees of exophoria for distance is compatible with perfect converging power and normal ability to overcome prisms, base out.

Fourth, he does not feel that exophoria in anisometropia and other conditions interfering with binocular vision represents necessarily, or even frequently, a reversion to the lower type, a sort of atavistic phenomenon. His explanation is that, owing to the anisometropia, etc., the two retinal images are of different size and distinctness, and it is correspondingly difficult to fuse them. If the patient gives up the fusion effort and sees double it is for his interest to throw the images as far apart as possible, so that they shall often confuse each other less, and this he does. The often spasmodically varying character of the exophoria for distance accords with this view.

Fifth, as regards the use of prisms for constant wear, Dr. Duane is opposed to them, because, while serviceable for a time, they seem in the long run to be detrimental. The untoward efforts may not occur until after they have been worn for a year or so. Not infrequently he has had patients come to him who have worn prisms for a long time and who say that, while at first comfortable, they have later become uncomfortable, and such patients he finds are almost always helped by removing the prisms. Again, prisms, base in, he is sure tend to increase the exophoria for near as well as for distance; i. e., tend to cause a true convergence insufficiency.

Sixth, Dr. Duane says that operating is a last resort, but when the indications are clear for it it does give gratifying results. His rule is: (a) With large exophoria for distance and less, or at least very little more exophoria for near, with good converging power (close convergence near point) and with eyes that can be and have been suitably trained to converge and see binocularly, he does tenotomy of one or preferably both externi. (b) With little exophoria for distance and low diverging power combined with exophoria for near and little or no converging power (remote convergence near point), he does advancement of one or both interni, with tenotomy of the externi. (c) With marked exophoria for distance and near with low or no converging power, and high converging power he does advancement of the interni.

It is understood that the operations are preceded by thorough orthoptic treatment.

DR. MARK D. STEVENSON, Akron, Ohio, said that convergence is chiefly stimulated by the desire for a single binocular stereoscopic vision. It is this desire which creates the so-called initial or tonic convergence which is required, so that a distant object may be seen singly, and it also compels convergence in association with accommodation in seeing close objects. The eyes can usually converge for a much nearer object than they can accommodate for, and this last part of the convergence act is done solely in the interest of single vision. Accommodation and convergence are usually associated only in the central act of convergence and not in its beginning or ending. Those under the effect of a cycloplegic, the old, and some myopes having no accommodation, often have good convergence. In testing for the muscle balance at the distance, the desire for single vision should be eliminated so far as possible, e. g., by making the objects seen with each eye dissimilar, as with the Maddox rod or by displacing the images by means of prisms, so that they could not be fused. However, in testing convergence which depends primarily on the desire for single vision this desire should not be suppressed, but the amplitude of convergence, which is of chief importance, should be determined. This is easily done by first determining the negative convergence, if any, in meter angles and then the positive convergence. The convergence near point may be found by means of a small light, but it is closer to the patient if a small white object on a black background is used, and Dr. Stevenson usually finds the convergence near point considerably closer to the patient than does Dr. Reber. In the *Ophthalmic Record*, July, 1904, Dr. Stevenson described a simple instrument by which the muscle balance at the ordinary reading distance during accommodation for that distance can be determined in a few moments, the patient looking closely at the small figures. By this means the degree of convergence for the reading distance, stimulated only by the accommodation for that distance, may be better determined than by the Maddox rod, as it is not so easy to accommodate for a light. The patient might accommodate for the red streak of light which, seen through the rod, often appears to be at a different distance from the light, and thus over- or under-stimulate convergence.

Dr. G. C. Savage, Nashville, directed attention to some points of vital importance. First, no test of the lateral muscles, he said, is worth anything when made under the influence of a mydriatic. The relationship between convergence and accommodation is such that if one takes away the accommodative power the converging power is disturbed, and one can not get reliable results.

Second, judgment of verticality, horizontality and obliquity is a gift and not an acquisition. He disagreed with Dr. Reber's statement that women can not judge this as well as men; a child can judge it as well as a man and so can a woman. A third point is this, that there is a distinct meaning when there is exophoria in the near and not in the distance, with young people, and if the physician does not understand that and prescribes full-strength convex glasses under a mydriatic he gets the patients into trouble. If a patient has exophoria in the near and not in the far, that patient has a powerful ciliary muscle, which, with a slight impulse from the brain, will focus rays of light from the page easily. Slight excitation of the accommodative center produces a correspondingly slight excitation of the converging center, and hence the feeble convergence. Now if the ophthalmologist prescribes full-strength convex glasses for a hyperope who has exophoria in the near and not in the distance, that patient will never accept those glasses. They will cause suffering until removed. If to such a patient, with, say, diopter of hypermetropia, the physician gives a one-diopter minus lens, he stimulates accommodative effort and so stimulates the convergence center, and comfort comes to the patient.

Dr. F. S. de Lue, Boston, said that in testing his cases for errors of refraction, he examines all for external muscle insufficiencies, and is surprised at the frequency with which exophoria appears when the hyperphoria has been relieved. Generally, the balance soon becomes re-established, and these patients do not complain, or if they are disturbed, it is not for distance, as a rule, but for near work, and a prism, base in, generally for near only, used a short time, gives the needed relief.

Dr. Oscar Wilkinson, Washington, said that there is a certain class of cases in which we get the most gratifying results from the use of prisms. He does not believe in using prisms for every case of exophoria, but when a patient fails to get relief from the correction of the error of refraction and comes back with asthenopia symptoms immediate relief can often be given with 1 or 1.5 degree prisms, base in. In regard to exophoria increasing under the use of prisms, he does not believe we will, as a rule, observe any appreciable increase in the exophoria from the use of the prism if the examination is made with sufficient care in the first instance. It should be made several times under different circumstances, i. e., when the patient is rested and when tired. In the treatment of exophoria an operation is indicated when all other means fail. In cases with more than 10 degrees of exophoria, tenotomy is the operation of choice; in cases with less amount the tucking or advancement operation is indicated.

Dr. Wendell Reber, Philadelphia, said that when he stated that he thought low degrees of exophoria were mostly productive of symptoms it was because they are overcome. Some patients with 3 degrees have more intense symptoms than those with 12 degrees. He called attention also to the fact that prisms for permanent use are not ordered for many cases. It is one of the last resorts and he submits that prisms for constant wear may be absolutely justifiable even though the exophoria does sometimes increase. He agreed with Dr. Duane that the cover test is the most valuable for testing exophoria for distance, but does not agree that it is for the near point. He thinks the small electric light is very valuable. He said that he wished he could feel, as Dr. Stevenson does, that we do increase the power of muscles by exercise, but he does not. He thinks that we simply teach these patients to use a coördination which they already have. Frequently the exophoria decreases and the symptoms subside.

CEREBRAL DECOMPRESSION.

PALLIATIVE OPERATIONS IN THE TREATMENT OF TUMORS OF THE BRAIN, BASED ON THE OBSERVATION OF FOURTEEN CASES.*

WILLIAM G. SPILLER, M.D.
Professor of Neuropathology and Associate Professor of Neurology in the University of Pennsylvania.
AND
CHARLES H. FRAZIER, M.D.
Professor of Clinical Surgery in the University of Pennsylvania.
PHILADELPHIA.

Palliative operations in cases of brain tumor are not new, and the temporary benefits to be derived in this way have been fully recognized by many physicians during many years. It has seemed time well spent to examine some of the reports of cases treated by trephining, or other method of opening the skull, for the relief of pressure when a tumor could not be localized, or if localized could not be removed. Unquestionably many cases have been omitted, and yet I have collected sufficient to demonstrate that palliative treatment has an important place in cerebral surgery.

REVIEW OF LITERATURE.

Annandale[1] said, in 1894, that more than twenty years previously he had opened the skull of a patient whose symptoms were those of general brain pressure and, although no special condition was found, temporary relief was marked. Another case of this kind, he says, was operated on by Sir Joseph Lister in the same wards with success. In 1889, Annandale removed a piece of bone from the skull because of intense headache, following an injury of the head years previously. No abnormal condition was found, although the dura was incised. The patient made an excellent recovery and was perfectly cured. Annandale remarked that when no localized symptoms of brain tumor exist an exploratory operation may be performed, and experience has shown that in some of these cases the operation has been useful in taking off general pressure and in a few instances has even been followed by shrinking or degeneration of the growth. Again, a growth may give rise to effusion of fluid or to hemorrhage, and the symptoms caused by these conditions may be at least temporarily removed by the operation.

Sahli,[2] in 1891, spoke of improvement from palliative operations. The tumor in one case was supposed to be in the cerebellum. Vision improved and headache disappeared after a palliative operation. The patient (a boy) died some months later and no necropsy was obtained. Sahli thinks that two trephinings remote from each other give more relief of pressure than one. Sometimes Nature performs a palliative operation, what he calls *Selbsttrepanation*. In consequence of the pressure the skull becomes thin at the region of the Pacchionian bodies and openings may occur, and in one case he saw the brain protruding through several such openings.

The palliative operation, he thinks, is not ideal, is not without danger, and improvement is only temporary. In one case of prolapse of the brain he observed unconsciousness immediately followed by death. Acute prolapse of the brain may impair the function of the rest of the brain. He recommends small trephinings in preference to large.

[2] Hermann Sahli: Volkmann's "Sammlung klin. Vorträge Innere Medicin," Nos. 1 to 29, 1890-1894, p. 300.

In 1891, White[3] described a number of cases of epilepsy in which improvement followed operation, although nothing abnormal was found.

In 1893, Horsley[4] said that the removal of excitatory symptoms by opening the skull is a marked phenomenon, convulsions ceasing. In one of his cases in which the diagnosis of tumor of the middle cerebellar peduncle was made, the skull was opened only to relieve the pressure, and the cerebellum protruded almost an inch through the trephine hole. The symptoms of tumor soon disappeared, and six months later the man felt perfectly well. He survived eighteen months, and during this time had few attacks. Only a small cavity was found.

Horsley thinks that some tumors are so interfered with in their nutrition by opening the skull and suddenly altering the pressure therein that they forthwith degenerate. In another of his cases the tumor was too large for removal, but the patient survived for over two years, with disappearance of the attacks and improvement of the hemiplegia. The tumor at the time of the operation was obviously malignant and rapidly growing, but had later undergone complete destruction by the mere exposure at the time of operation. Such a result, he says, can not be anticipated or expected as likely to follow, but it is an argument in favor of opening the skull for the purpose of palliating a condition which can not be cured.

Horsley says, also, that he has found in every case the effect of opening the skull has been to remove the headache and, further, that in cases where it was known before operation that the tumor could not be removed relief from severe pain afforded by opening the skull persisted until the patient died. The simple and safe procedure of opening the skull should be undertaken when drugs fail. At the Berlin Congress Horsley pointed out that opening the skull caused the swelling of the optic discs to subside, and that the subsidence may proceed steadily to complete recovery, provided atrophy has not previously begun. If atrophy has commenced the condition is hopeless. Vomiting is dependent on the degree to which intracranial tension is raised, and, as a rule, this symptom disappears when the skull is opened.

Jaboulay,[5] in 1893, obtained good results by trephining in a case of tubercle of the brain without opening the dura. The prognosis from trephining, he thinks, is better the more circumscribed and superficial the lesion.

Caton and Paul[6] trephined the skull in a case of acromegaly in 1893. The dura bulged in the opening. The operation relieved the headache, and the remaining three months of the patient's life were comparatively comfortable.

Macewen[7] did a palliative operation in 1889 in a case with symptoms of cerebellar tumor. The patient experienced great relief. After a week tuberculous tumors were removed from the cerebellum.

Taylor[8] reported a series of cases of brain tumor to show that there is almost invariably a subsidence of optic neuritis after operation whether the tumor is removed or not. This fact, he says, was known to Horsley so long ago as 1888. In discussing Taylor's paper Horsley said that if there is any atrophy present no amount of reduction of pressure within the skull will produce the slightest change or afford the slightest relief in respect of the loss of vision. If there be commencing atrophy, after operation the neuritis that may be present will disappear, but the atrophy is permanent; opening the skull, therefore, is not justifiable if the atrophy is well marked. Horsley was probably referring to the operation only in so far as vision is concerned, as the operation may relieve some of the other symptoms, even though it may be too late to restore vision. The optic neuritis may disappear, Horsley says, even though the dura is not opened.

In a case reported by Keen[9] in 1894, the diagnosis of intracranial tumor was made, but the growth could not be located. Trephining was recommended with a view of relieving intense headache. The tumor could not be found. The bone was not replaced, and, although the brain bulged greatly, headache and hallucinations entirely disappeared, and the man became a quiet and tractable patient. He died four and a half months after the operation, having been much relieved during this time. The operation was performed in 1892. In another case, also, much benefit was obtained by a palliative operation.

Bruns,[10] in a case of brain tumor in which the tumor could not be found at operation, improved the patient's condition by opening the skull. By the end of the third week very little choked disc remained, attacks of blindness no longer occurred, headache was much less severe and vomiting ceased. Similar improvement he had noticed in two other cases of brain tumor after trephining.

Byron Bramwell,[11] in 1894, said that he had advocated trephining for the relief of symptoms in his book. "Tumors of the Brain," published eight years previously, but that he would advocate the operation still more strongly in 1894 in cases in which there is a great increase of intracranial pressure and drugs have failed. When he published his book he had not been aware that Grainger Stewart or any one else had recommended the operation. In many cases the headache is intense, and it has been shown that in some of these cases sudden death occurs, apparently as a result of the mere severity of the pain and sudden inhibition of the action of the heart. In other cases in which the intracranial pressure is greatly increased, the patient dies suddenly in an epileptic fit or as the result of failure of respiration. Opening the dura reduces intracranial pressure and relieves headache, optic neuritis and other symptoms.

In 1894 Kammerer[12] reported a case of supposed tumor of the brain in which double trephining was done for the relief of pressure. The headache disappeared, vomiting ceased for several weeks and then occurred occasionally. The motor power of the right side (previously this side was paretic) improved and some sensation returned. The dura was not incised.

Wyeth remarked that he had trephined in two cases with symptoms of brain tumor and, finding no tumor, had sewed up the dura, but had not replaced the bone: improvement had followed the relief of pressure.

Sänger,[13] in 1894, reported a case of brain tumor in which after opening the skull and dura prolapse of the brain with improvement in the symptoms occurred.

In one of the cases of tumor reported by E. Albert[14] in 1895, in which palliative trephining was done, headache disappeared, but vomiting persisted. The dura probably was not opened. Later trephining was done on the other side of the head, but vomiting persisted. The relief afforded was in regard to headache and might have been greater if the dura had been opened.

In another case in which trephining was done for brain tumor the dura was punctured. Headache became at once less severe, but the improvement was only temporary. In another case after trephining apparently without opening the dura, vision improved and headache and vertigo disappeared. The symptoms returned and the dura was opened. The operation was not very successful as a palliative means.

Schlesinger,[15] in a case of brain tumor, had a large protrusion of the brain as a result of the operation. The protruded portion could not be replaced, nor was it excised, and when the patient was presented he had a subcutaneous tumor on his head as large as a fist. The general condition improved as a result of the operation, the palsy diminished, the Jacksonian convulsions ceased on the third day after the operation, the choked discs and headache disappeared. Seven weeks had elapsed since the operation at the time of presentation. A later report of this case states that the improvement lasted several months and then the symptoms returned rapidly and death soon resulted. The entire right cerebral hemisphere was replaced by a gliosarcoma.

Decompressive trephining, a term employed by Jaboulay,[16] performed for brain tumor, according to this author, has proven to be of some benefit, more often not. When done for the relief of inoperable tumors. the results are not always brilliant. He speaks of astonishing results produced by trephining in the cerebellar fossa in a case of basal tumor; the pain ceased and the vision improved. The patient lived four and a half months after the operation. Jaboulay seems to believe that the relief in palliative operations is greater for tumors of the cerebellum and adjoining parts than for tumors of the cerebrum.

Broca and Maubrac[17] ascribe to Horsley the honor of being the first to describe carefully trephining as a palliative operation in brain tumor, although scattered references to the subject are found in the literature, and they refer to Annandale and Lister. Horsley recommended making a large opening in the skull without opening the dura. Sahli, they say, recommended excision of the hernia that is produced by opening the dura. especially as the portion of the brain involved in the hernia is impaired in its function. They say that Kocher did operate in this way on a child in the service of Sahli for a tumor not localized, but probably in the cerebellum. A hernia of the cerebellum was excised and benefit resulted. Broca and Maubrac employ the term "cerebral decompression." The palliative operation, they think, exposes the patient to the danger of shock, and when the operation is performed at an advanced period of the disease death is not exceptional. When the patient survives, the most distressing symptoms are lessened or disappear entirely, and. therefore, the palliative operation should be employed. It does not cause more rapid growth of the tumor. Exploratory trephining, when the diagnosis of location has been incorrect, has taught us that cerebral decompression may give important results. These authors express themselves in favor of partial removal of a tumor when the whole can not be excised. but are undecided as regards Horsley's view that partial ablation may retard the growth of the remaining portion. They report two cases of tumor in which palliative operation was beneficial.

In 1895 J. J. Putnam[18] remarked that he knew of one patient who, in consequence of simple opening of the skull, had been free from pain for many years, though blind. He said he had seen relief from pain by large openings in the bone in several cases of brain tumors.

Shultze's[19] results from palliative operation in brain tumor were disappointing, as recorded in his paper published in 1896. He speaks of it as often dangerous, but at times beneficial.

Ludwig Bruns[20] thinks that when the tumor can not be removed or only a small part of it is removable, trephining does not affect the focal symptoms, but causes the general symptoms quickly to disappear if the opening is large. Consciousness returns, headache, vomiting and choked discs disappear. In two of his cases the patients, who had hovered between life and death, had been able to walk again after palliative operations. In one of his cases (glioma of the occipital lobe) improvement lasted several months; in a second case it lasted some weeks. As headache in many cases does not return at all, the recurrence of symptoms is not so distressing and the patient passes into coma. The tumor, by growing through the opening, removes the pressure on the lymph tracts within the skull. Bruns says the opening in the skull must not be too small, and the dura must be opened.

Clarke and Morton[21] report a case of tumor of the brain without localizing symptoms, in which a large area of the skull was removed for relief of intracranial pressure and the dura was not incised. Headache disappeared. They remarked that Beevor and Ballance thought that removal of bone alone without incision of the dura was not likely to relieve intracranial pressure, but they (Clarke and Morton) believe that the actual increase in the bulk of the cranial contents may not be considerable if the tumor is small, and the bulging of the dura mater even to a very limited extent may be sufficient to relieve the increase of the intracranial pressure caused thereby. Clinical evidence in Caton and Paul's case, as in their own, showed distinctly that removal of an area of bone alone is sometimes sufficient. Except for the recurrence of fits five months after the operation, the trephining was of great benefit in Clarke and Morton's case. Optic neuritis subsided, leaving some consecutive atrophy, but the patient had good vision, was entirely free from headache and vomiting, except once during the last series of fits, had recovered his mental powers and had a comfortable existence.

Alfred Wiener[22] reports a case of irremovable tumor. After opening the skull, headache and convulsions disappeared for about two months, but the tumor grew through the opening of the skull, attained considerable size on the outside of the skull, and the symptoms returned. Wiener speaks in favor of trepanning in cases of brain tumor, even when there is no other hope of success than the relief of the general symptoms.

Rohmer[23] has collected a large number of cases in which the palliative operation in tumor of the brain had a beneficial effect on vision.

von Bergmann[24] has called attention to the fact that in contrast to those cases in which improvement was pronounced after palliative operations for brain tumor others are recorded in which no benefit was obtained, and, indeed, the symptoms were made worse. The improvement is only temporary and in some cases has been of very short duration. The operation also is dangerous. Improvement has occurred after merely opening the skull or after opening the dura also; surgeons, therefore, he said, preferred to remove a large piece of bone and leave the dura intact, but, as cerebrospinal fluid can escape only after the dura is opened, the incision of the dura is a necessary part of the palliative operation. There was a tendency, he said, to stop at a palliative operation, and this must be strongly combated. The future of the surgical treatment of brain tumors lies in the advancement of diagnosis, and in this way the almost thankless palliative operation may be changed to a radical cure. As the escape of cerebrospinal fluid is more important than the opening of the skull, v. Bergmann recommended lumbar puncture. Since v. Bergmann wrote his book experience has shown that lumbar puncture in cases of brain tumor may be dangerous. He has been pessimistic both as regards palliative and radical operations for brain tumor. He gives a long list of cases in which exploratory and palliative operations were done, but almost all of these were attempts at removal of a tumor. In his book (1899) occurs the expression, "decompressive trepanation." He refers to a case reported by Remsden in 1825, in which trephining was done for headache.

Sänger,[25] in 1894, reported two cases to show that under certain circumstances trephining is proper, even when a tumor can not be removed. In 1899 he presented a case of brain tumor in which a palliative operation had been performed. Inunctions were at first effective, but later the symptoms became very severe. An opening was made over the cerebellum and the cerebellar lobe at once protruded; when the dura was incised much cerebrospinal fluid escaped into the bandages for more than three weeks. After the operation vomiting and headache ceased and full recovery seemed possible. Choked disc disappeared, and vision improved so much that the patient was again able to read. The gait also improved and ataxia became hardly noticeable. The operation was performed Aug. 7, 1899, and the presentation of the patient was made Nov. 14, 1899.

Babinski,[26] in 1901, reported a case in which a tumor could not be found after the cerebral dura was opened, although the symptoms had been so severe as to make an operation desirable. The headache and vomiting ceased after the operation, which was performed January 14. The choked discs disappeared by January 30. The presentation of the case was made Feb. 7, 1901. In another case Babinski observed signs of an intracranial disease. The patient had an intermittent discharge of cerebrospinal fluid by the nose. Headache was lessened by the escape of fluid and became more intense when the flow ceased. Nature in this way produced decompression, he says. This case is not unlike some others reported in the literature in which Nature has effected a means of relief for intense intracranial pressure, and bears a resemblance to a case observed by me in consultation with Dr. Laplace and reported in this paper (Case 1).

A. Sänger[27] presented a case in which he had made the diagnosis of cerebellar tumor and an opening was made over the left cerebellar lobe. The improvement was marked, and Sänger believed that either the tumor had undergone a retrograde change or the condition was hydrocephalus. Of eleven cases in which a palliative operation was performed, the symptoms were much lessened in ten. The time for operation that Sänger chooses is the beginning of impaired vision. When the opening is made over the cerebellum the dura must not be opened immediately.

In 30 cases of brain tumor studied by Leslie Paton[28] that were operated on, useful vision was saved in 22 and the vision was as good as before the operation in 18. It is impossible to draw conclusions regarding his cases in which a tumor was removed and those in which a palliative operation was performed. In the discussion following Paton's paper J. S. Risien Russell said he had no doubt that trephining was of great value in saving sight. He never hesitated to recommend the operation, even in cases in which there was no chance of either localizing the tumor or removing it, for by relieving the intracranial pressure alone sight could be saved. His experience had been that removal of bone alone was not sufficient; it was usually necessary to open the dura in order to obtain sufficient relief of pressure to bring about a subsidence of the optic neuritis. Paton also expressed himself in favor of opening the dura, as he did not believe merely opening the skull was of much benefit. In two cases only the cranial cavity was opened, and blindness developed in both.

Codman[29] says:

> In 28 of the 36 operations the attempt at a radical removal of the tumor was made, and in the eight worst cases only was it decided to do only a palliative operation. I think we may almost say it is certain that if in no case the attempt at radical removal had been made and, instead, a simple operation for the relief of pressure had been done through an intermuscular incision over a "silent" portion of the cortex, the mortality would have been greatly diminished and the percentage of improvement been made much greater. I do not mean to say by this that radical operation in the hands of a surgeon who has made a specialty of brain work is not justifiable, but that in the hands of most of us, a simple palliative operation will be far better in the long run.

In my opinion, only one who has made a specialty of brain surgery should attempt to remove a brain tumor.

J. J. Putnam[30] reports cases of palliative operation. In Case 2 marked relief from terrible headache and optic neuritis followed the making of a large trephine opening in the parietal region, and this, too, although the bone was replaced. This improvement was attributed to the escape of cerebrospinal fluid, which gushed in large quantities from the wound in the parietal dura. The tumor was a glioma of the lateral lobe of the cerebellum. In Case 3 a large tumor mass protruded through the trephine opening, pushing the skin before it. A measure of relief followed the operation. Recently, in association with Watermann, he has reported other cases. Lund[31] also has reported improvement from the palliative operation in cases of tumor of the brain.

Cushing[32] has reported recently cases in which the palliative operation has been of much benefit.

DR. W. W. KEEN'S CASES.

I add condensed notes of two unreported cases in which palliative operation was performed by Dr. W. W. Keen, with improvement in each.

[32] "Surgery, Gynecology and Obstetrics," vol. 1, 1905, p. 297.

Case 1.—Jan. 3, 1901, E. H. M., aged 26, complained of failing vision and had later several attacks of temporary blindness. Among the first symptoms were severe headache on the right side and vomiting, later the pain shifted to the left side. He was found to have extensive optic neuritis. He has a little vision now in the left eye but is blind in the right eye. He has sharp boring pains which shoot from the upper occipital region to the back of the left ear. The patellar reflexes are exaggerated. Dr. de Schweinitz, Dec. 17, 1900, found optic neuritis passing into atrophy.

Dr. Keen, Jan. 30, 1901, made an osteoplastic flap over the left parieto-occipital region. The dura was very tense. Four small openings were made in the dura, but nothing abnormal was discovered. The brain was punctured in the attempt to reach the lateral ventricle and the attempt probably was not successful. The piece of bone was removed entirely. The patient was discharged February 18, almost entirely relieved of his headache.

At Dr. Keen's suggestion, I made inquiries regarding the present condition of this man and received the following letter, dated April 20, 1906: "I am wonderfully improved and relieved as to pain, can not see except to distinguish between night and day, have not been bedfast for a year or more, at intervals have severe pain, say every week or two, lasting from twelve to twenty-four hours, after which brain is very sore. Since last July have been having a discharge of the left nostril, of a watery-like fluid, since that the pain is not quite so severe."

Case 2.—Feb. 5, 1903. E. B., aged 37. During the summer of 1894 a small tumor developed in the scalp on the posterior portion of the right parietal bone producing headache and a sensation of pressure. In the summer of 1895 this mass was removed. His physician stated that it was a fatty tumor. All the pain and pressure symptoms disappeared and he was perfectly well.

After several months the headache and pressure sensation gradually returned; simultaneously with the onset of the headache his eyesight began to fail, and for the last two months he has been partly blind. He has had frequent vomiting, but he attributes this to the iodids. Ataxia was noticed in the finger-to-nose test. His gait is ataxic with a tendency to fall to the right. Lateral movements of the eyeballs are ataxic. Patellar reflexes are minus. Dr. Sweet found papillitis passing into optic atrophy in both eyes.

Feb. 11, 1903, Dr. Keen exposed the cerebellum over nearly one-half of the right half of the occipital bone. The dura was extremely tense on palpation. The patient was discharged ten days after the operation entirely relieved of his headache and with the wound healed.

Dr. John T. Howell wrote to me, April 23, 1906, that the patient died in a hospital in England, July, 1904, after an operation in February of the same year. The skull was opened above the ear and a large tumor was taken from the brain. After returning from the Jefferson Hospital, in 1903, the patient's improvement was of short duration.

(To be continued.)

PHARMACOPEIAL OR PROPRIETARY PREPARATIONS: WHICH?

JOHN RITTER, Ph.G., M.D.
Clinical Instructor, Department of Chest, Throat and Nose, Rush Medical College.
CHICAGO.

The medical profession is confronted with the difficult task of providing an effective method of checking the practice in vogue with many of its members of prescribing and recommending various proprietary remedies, many of which are most fraudulent.

It is sometimes difficult to draw hard-and-fast lines regarding what really constitutes an ethical preparation in contradistinction to a so-called "nostrum." It is not good practice to condemn *in toto*, with one stroke, all proprietary preparations, for undoubtedly ethical, nonethical and even many nostrums possess some therapeutic properties, since in the composition of most of them certain well-known drugs are used

Irrespective of the composition and therapeutic value of the medicament, the medical profession brands as nostrums all which make claims to possess curative properties wholly at variance with well-known laws of drug administration. At times the physician is greatly perplexed and confused by the vast array of preparations which are offered, recommended and extolled for the treatment of various disorders and maladies, and through this uncertainty he has at times been led to prescribe proprietary preparations when in *reality* he has been of the opinion that he was recommending and prescribing strictly pharmaceutical remedies.

It would be an excellent plan if both practitioners of medicine and members of the pharmaceutical profession would look very carefully into the composition and combination of all new chemical, synthetic and Galenical preparations (not excluding "patented" nostrums which are from time to time offered to physicians as valuable therapeutic agents), would examine the preparations and their literature very carefully and would report the findings to the various medical or pharmaceutical societies. Then, should the preparations show any extraordinary merit, they might devise preparations of equal efficacy, if not superiority, and probably at very much less cost to the consumer.

Our standard, the United States Pharmacopeia, has already shown us the way and can always be our guide. For instance, at present there is on the market a great and ever increasing number of acetanilid combinations, differing very little in composition, but under very different and fanciful names. In order to avoid this confusion of names, and in order to harmonize the medical profession, the committee of revision of the United States Pharmacopeia has ordered incorporated into the United States Pharmacopeia the preparation known as *pulvis acetanilidi compositus*. Therapeutically it matters very little if in all these various preparations the amount of citrate of caffein is 1/50 grain more or less, or if the amount of bicarbonate of soda is ½, ¾ or 2 grains in each dose, or if the alkaline salt be bicarbonate of soda, or potassium carbonate, or carbonate of ammonia, each of which is added simply as a solvent for the acetanilid. The same rule could be used in all similar preparations which are now or may be offered.

Another example: Since the reintroduction[1] of earth into the materia medica as an antiphlogistic application a number of preparations with fanciful and arbitrary names—names, in most instances, suggestive of an antipyretic—have been offered to the medical profession, and here again, in order to extricate the physician from this chaos, the United States Pharmacopeia has come to the rescue and has formulated and offered to the profession a most efficient and reliable combination in "cataplasma kaolini."

It has taken many years to bring the different liquid preparations of opium, which at various times were extolled by irresponsible vendors and charlatans as boons to humanity, to assuage suffering, under a distinct class. Tinctura opii, tinctura opii camphorata and tinctura opii deodorata of indefinite strength were for years sold under various names by ignorant and unreliable persons, a very dangerous practice, considered from the present standpoint of drug administration. Tinctura opii of indefinite strength was then generally known as laudanum, Abbe Rousseau's drops, tinctura thebaica, tinctura meconii.

---

[1] The use of earth or clay as a topical application is as old as medicine itself. Applications of earth or clay or of earth mixed with oil or fat were the only remedies used on painful surfaces by the poor in ancient times. Then followed the use of earth and molasses, hot or warm sand or salt, then bread and milk poultices, linseed meal, and now it is popular to use earth and glycerin.

Tinctura opii comphorata still has some adherents, especially among the laity, under the old names of Bateman's pectoral drops, Godfrey's cordial, paregoric, Schultz's antispasmodic drops, while tinctura opii deodorata is still occasionally prescribed by old practitioners as McMunn's elixir. Now the therapeutic value of all these different preparations of opium depends on the definite percentage of the alkaloid morphin present in the various grades of the drug used. The various pharmacopeias of the different nations, and especially the U. S. Pharmacopeia, have directed that, in order to secure uniformity in medication and reliability in results, all grades of opium used in the preparation of the various pharmaceutical preparations containing opium must conform to a standard of at least 12 per cent. of morphin assayed in the grades of opium used. In times gone by, when the different preparations of opium were vended under these many different names, they were all more or less unreliable and even dangerous, as they were prepared without any knowledge or regard to the amount of morphin contained in the drug. It is well known that some grades of opium assay as low as 1 per cent. and others as high as 16 per cent. and even higher. Scores of other and of similar examples can be mentioned.

Tinctura aloes et myrrhæ, under the name of Elixir Paracelsus, was known in remote times. Tinctura benzoini composata as a topical remedy had a wide reputation under the euphonious names of Friar's balsam, Turlington's balsam. Linimentum saponis was known as Stear's opodeldoc, infusum sennæ compositus as Vienna draught, not to mention Dover's powders, Donavon's solution, Labarraque's solution, Goulard's extract, Basham's mixture and many others.

Take, for example, the various combinations and mixtures of cod-liver oil which are now on the market and with which most physicians are familiar either through the medium of the daily press or through the advertising columns of medical or pharmaceutical publications, by the liberal supply of samples or by waste-basket literature. The literature is usually very adroitly worded, calling the attention of the physician to a pleasant and palatable preparation of cod-liver oil, and the physician who prescribes these preparations is flattering himself that probably in a given case of pulmonary affection, or in the convalescence from an infectious disease, or perhaps in the after-treatment of typhoid or pneumonia he is giving a tissue builder, a nutrient, a food in the form of an elegant cod-liver oil medication, when, as a matter of fact, he is doing nothing of the kind. It is not even indicated in the literature or on the label that the preparation contains cod-liver oil, although the words cod-liver oil appear in glaring big type. What the circular or printed matter generally says is: This preparation *represents the value* of 25 per cent., 33 per cent. or 50 per cent. of cod-liver oil. But it does not say that it contains a minim of cod-liver oil. [The alcohol soluble admixtures of cod-liver oil, consisting of biliary acids and bile salts, trimethylamin, volatile ammonia, some fatty acids and traces of iodin, phosphorus and phosphoric acid, sulphur and sulphuric acid, with some coloring matter wholly inert, is made by the addition of expectorants, anodynes and corrigents into a pleasant-tasting elixir, cordial or tonic, but not a trace of cod-liver oil can be found in it.] These preparations may possess some therapeutic properties and undoubtedly may be very useful in the treatment of bronchitis and in pulmonary affections generally. Similar preparations, but of definite strength and uniformity, may be devised if the profession must have such combinations.

At present, by means of samples, circulars and pamphlets, through the public press and in some of our journals and magazines intended to be read at the fireside and in home circles, even by some of our medical publications, various preparations are advocated and recommended in the treatment of real or imaginary uterine diseases and are usually mentioned as uterine tonics. Although some make claims for good wholly unwarrantable, still a few grains of truth may be found in all the chaff. Reliable and honest pharmaceutical houses have taken the cue and have formulated preparations, some of undoubted merit, which may be used with more or less good results in the treatment of the various uterine disorders. These pharmaceutical houses have sampled the medical profession liberally, both by the way of trial medication and printed matter, but especially the latter, and from this practice the physician has acquired the pernicious habit of prescribing these so-called uterine tonics. In the National Formulary, a book which may be called an appendix to the United States Pharmacopeia, and which is compiled for the purpose of furnishing to the medical profession good and reliable formulæ for all unofficial preparations, such as physicians may unhesitatingly prescribe, a good and an efficient combination suitable as a uterine tonic may be found.[2]

If the physician would devote about half an hour each week looking over the United States Pharmacopeia, a good dispensatory, the National Formulary or a standard work on materia medica or therapeutics, he would soon acquaint himself with good, reliable and accurate formulæ and remedies, preparations which he need not hesitate to prescribe; preparations on which he could rely at the bedside, where, after all, the supreme test of the physician's skill must be demonstrated; and instead of continually racing after strange gods it would eliminate from his mind all the various uncertain compounds and mixtures—nostrums—with which he is now burdened.

Such time would be well spent. It would familiarize the physician with many a good medicament and teach him its composition, and, most important of all, it would teach him what he might expect from it therapeutically. The difficulty lies in this: the average physician devotes too little study to materia medica and therapeutics. A better acquaintance with the United States Pharmacopeia and with materia medica and works on therapeutics is most essential in combating the ever-progressive proprietary medicine evil.

170 Colorado Ave.

---

[2] Elixir viburni opuli compositum, in the National Formulary, is as follows:

Fluid ext. viburnum opulus	f. ℥i¼	38|
Fluid ext. trillium	f. ℥iss	75|
Fluid ext. aletris	f. ℥i¼	38|
Compound elixir of taraxacum	℥xi	330|

Pilocarpin.—Dr. S. West employs pilocarpin in both uremic and diabetic coma, giving from 1/12 to 1/6 of a grain hypodermically and repeated at intervals. He has never seen anything but good come of it. Pilocarpin is more reliable and less dangerous, he thinks, than the infusion of jaborandi.—*Clinical Journal*, May 30, 1906.

Clinical Notes

TWO CASES OF INFECTION WITH TÆNIA NANA IN THE PHILIPPINE ISLANDS.

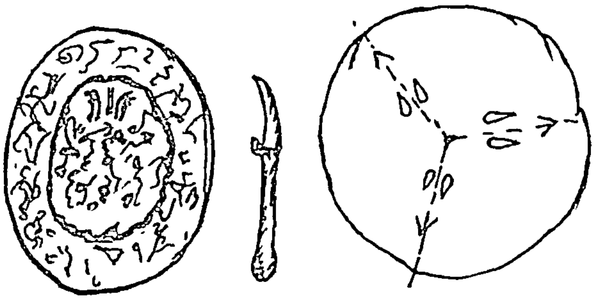
CHARLES L. FOSTER, M.D.
Lieutenant and Assistant Surgeon, U. S. Army.

During my tour of duty in the Philippines, two cases of infection with *Tænia nana* (*Hymenolepis nana*) came under my care, and a brief outline of the symptomatology in these cases and a description of the ova of the parasite may be of interest, especially in demonstrating the fact that infection with this tapeworm is not infrequent in the Island of Luzon and that the damage to the host may be severe.

NARRATION OF CASE.

The first case under observation was a private of E troop, 8th U. S. Cavalry. After the recent epidemic of Asiatic cholera in and around Manila, one squadron of the 8th cavalry was stationed along the Mariquina river, from which stream is derived the water supply of Manila, to guard the river from pollution. E troop took station at Mariquina, a town five miles from San Mateo.

Case 1.—The patient had marched with his troop from Fort William McKinley to Mariquina and soon after arrival was taken sick. Forty-eight hours later I saw the man. As several deaths from Asiatic cholera had occurred at Fort McKinley just before this troop left, it was feared that this man might have the disease.



Figs. 1, 2, and 3.—Ovum with inner membrane surrounding embryo. Hooklet with rounded extremity for musculature. Diagram showing arrangements of hooklets in three planes.

Symptoms.—When I reached Mariquina the man had nausea and vomiting, with frequent loose and watery stools; intestinal cramps, not very severe, and no cramps in the muscles of the limbs. He was very weak, but there was no collapse and the pulse was fairly strong and regular. Temperature: Mouth, 99 F.; rectum, 100.

Treatment.—The patient was transferred to the hospital at San Mateo by ambulance, and after taking a little cracked ice and brandy the nausea and vomiting were relieved.

Stools.—The first stool was examined. It was watery with a few flakes of brownish material scattered through it; not at all like the rice-water stools of cholera. Under the microscope there were seen epithelial cells in various stages of degeneration, fatty acid crystals, and bile-stained débris. The usual products of severe intestinal inflammation were not present. Hundreds of ova (Fig. 1) were seen. Each stool was saved (male fern had been administered on the second day after admission) and search made for the worms, but none could be found, and, after the first morning of the patient's admission to hospital, no ova were found. The intestinal antiseptics and purge administered before I saw the man, it is supposed, caused the expulsion of the worms; the stools were not carefully examined until the patient entered the hospital. He gained rapidly in strength and weight and was soon returned to duty.

Case 2.—The second case was under treatment one month later. The man is a member of the hospital corps.

History.—He gave a history of chronic diarrhea in 1898, contracted while in Puerto Rico. He was operated on in 1904 for appendicitis. For several months he has been troubled with constipation, loss of appetite, coated tongue, and distended and slightly painful abdomen. He is nervous and does not sleep well, and has abdominal distress after eating.

Examination of Stools.—The stools were formed, dark-yellow in color, with flakes of mucus scattered through them. Under the microscope, ova in every respect similar to those noted before, were found; and, also, many *Cercomonas intestinalis.* The man was put to bed and given a preliminary purge and two 3 c.c. doses of male fern. After several hours the stools were examined and about forty unbroken *Tæniæ nanæ* were obtained. Several of the worms were brought out by the purge.

THE OVA.

The ova are transparent and not bile stained, oval. almost round, in shape; about 30 microns in the short diameter and 35 microns in the long. The shell is very thick, not rigid, and not radially striated, and contains here and there coarse granules. Immediately surrounding the embryo is a delicate membrane (Fig. 1). The protoplasm of the embryo contains many granules of various sizes. Six hooklets are attached to each embryo (Fig. 2); these are arranged in pairs and their points almost touch the inner membrane. The curved points of the ends of the hooklets are directed from the center of the group, in three directions. The arrangement of the groups of hooklets, and the fact that in several of the ova the hooklets had perforated the membrane and were projecting into the shell almost to its outer surface (Fig. 4), and that in others the points of the hooklets were widely separated from each other and some distance from the membrane, suggested to me that perhaps the function of these hooklets was to free the embryo from the shell. Diligent search was made to see if any motion of the embryo could be observed. At length one embryo was found in active motion within the shell. The points of the hooklets were first drawn together and the whole armament thrust against the adjacent part of the surrounding membrane and into the shell; then the hooklets made a circular sweep around a point near their blunt extremities as a center, in three planes at angles of 120° to each other (Fig. 3). This thrust and sweep was repeated at the rate of about once in ten seconds. The motion continued for about one hour, at the end of which time the envelope had been cut through about three-fourths of its thickness. Motion then grew slower and soon ceased altogether. During the motion of the hooklets, motion of the protoplasm of the embryo could be traced by the granules contained

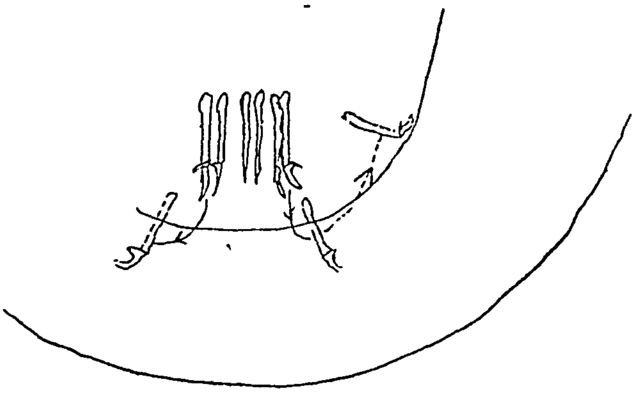


Fig. 4.—Diagram showing how points of hooklet are thrust into the shell and then swept around through it.

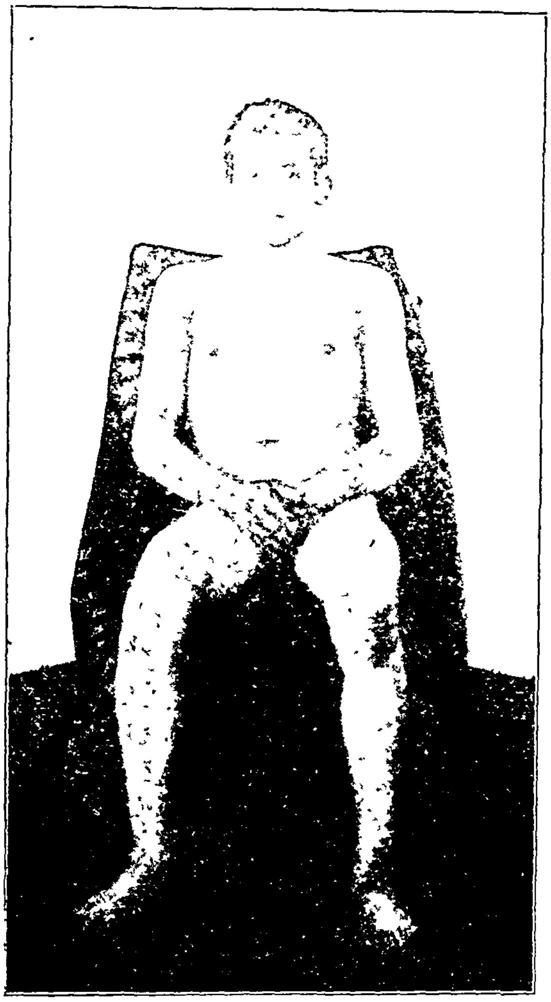
therein. No embryos free of their shells could be found. This movement was observed in the embryos passed *per anum* by both patients, also in those expressed by cover glass from the fresh worm obtained from the second case.

The parasite is found in several of the lower animals, especially rats, in which animal, it is stated, an intermediary host is not required.

ROCKY MOUNTAIN SPOTTED FEVER.

CHARLES E. MOOSER, M.D.
RENO, NEV.

I read with interest two articles on Rocky Mountain spotted or "tick" fever in The Journal, July 7, 1906. This fever exists in Nevada, but cases do not seem to be so numerous or so fatal as those occurring in Idaho, Utah and Montana. Here they occur almost, if not exclusively, among sheep-herders, so I am somewhat surprised that Dr. H. N. Mayo does not even mention this class, though they are plentiful in the states named.



About three years ago my first patient with "tick" fever came to me. I did not recognize the condition as such, hence can not say whether the patient, a sheepman, had been bitten by a tick. The infection was severe and I feared that I would lose the patient. He got up at the end of eight weeks, and recovered slowly thereafter, and in time became entirely well. The treatment in this case was symptomatic, as outlined by Dr. Mayo.

Within the past two months I have had six cases, five Frenchmen and one Spaniard, all sheep-herders. They came from three different camps (one of which seems to have acquired a reputation for having such cases yearly), two from each camp. Without exception all the men gave a history of one or more very recent tick bites. All the patients were severely infected, two especially so. None of the cases terminated fatally; all were typical cases. The Spaniard's case was the most severe, perhaps because he came to me later than the others, having tried to "fight off" the trouble. He came in an extremely emaciated condition, resembling the pictures of Cuban reconcentrados published in the papers during the Spanish war, and in marked contrast to the puffed features of the others. A very distressing phase of his illness was a cough resembling that of an advanced case of phthisis. Examination of lungs was negative and the results justified the belief that no serious lesions were present, as the cough disappeared with the eruption.

Unfortunately no special blood or other tests were made, owing to lack of facilities.

In great contrast to the first case mentioned all of these patients were practically well within three weeks—out of bed, etc.—final recovery being very rapid thereafter. With but slight exceptions, calling for some special drug, all the patients were given practically the same treatment. An initial dose of calomel and jalap, followed next day by quinin, 30 grains twice daily for one week (a little longer for the Spaniard), then in gradually diminishing doses until the temperature remained normal for two days.

Strychnin sulphate was given when necessary. A seidlitz powder or two was given every morning. Sponge baths were also given. No quinin was given in my first case. Other cases with which I am familiar, and in which quinin was omitted or given in small doses only, lasted, as did my first case, about two months. In those in which large doses were used the majority of patients recovered in from ten days to two weeks. The accompanying illustration of the patient in my last case (not a very good photograph) shows the typical eruption.

CONGENITAL MEMBRANE IN THE NASOPHARYNX.

RICHARD H. JOHNSTON, M.D.
BALTIMORE.

Patient.—Mrs. M. E., aged 35, was referred to me for examination and treatment of nose and throat.

History.—For a number of years she had had trouble with the right ear in the nature of a purulent otitis media. With the removal of the ossicles she experienced great relief from certain subjective symptoms while the discharge was reduced to a minimum. She complained of dryness of the nasopharynx which had existed for a long time and of disagreeable sticking and gagging sensations which combined to make life miserable. From her efforts to remove the secretion, nausea and vomiting ensued. There was constant tinnitus in the left ear.

Examination.—The nose showed nothing abnormal with the exception of a dryness of the mucous membrane. The pharynx was dry and parched and covered with a layer of thick grayish secretion which apparently came from the nasopharynx. The examination of the latter revealed a curious condition of affairs. After cleansing the posterior pharyngeal wall the mirror could be used with ease. Coming down from the roof of the nasopharynx and extending entirely across the cavity was a distinct membrane which divided the space into anterior and posterior parts. The membrane had its origin behind the openings of the Eustachian tubes, neither of which was visible. About the center of the membrane was a round perforation extending a little further to the left than to the right. Through the hole could be seen the lower two-thirds of the septum, the inferior and the middle turbinates on the left and a little to the outer side of the septum on the right. Above and to the right, midway between the opening and the lateral wall, and at the point where the membrane came off from the roof, was a second elongated opening much smaller than the first. The margins of both openings were perfectly smooth and clear cut. The membrane passed downward and became gradually lost on the posterior wall of the soft palate.

No tuberculosis or specific history could be obtained. From the large extent of membrane and from the clear cut margins of the openings, there can be no doubt that it was congenital. The nose was in fair condition and it seems proper to assume that the partial obstruction to nasal breathing had contributed in part at least to the extreme dryness of the throat. A proposition to attempt the removal of the membrane was declined by the patient.

Royet[1] has an article on insufficient nasal breathing caused by bands of tissue extending from the Eustachian tubes to the posterior wall of the nasopharynx. He cites two cases in which the destruction of such bands restored nasal breathing and relieved tinnitus of long standing. In a third case the bands adhered to the soft palate. In this case the mirror could not be used so it is impossible to say just what the character of the bands was.

Molinie has reported two cases of annular contraction of the nasopharynx. Courtdade in 1903 related that he had long recognized the fact that a cause of pharyngeal obstruction was the partition of the nasopharynx by filament-like bands.

Royet concludes: 1. That bands of tissue from the tube to the posterior pharyngeal wall can cause obstruction to nasal breathing which in most cases is slight. 2. In the majority of cases they are associated with other lesions of inflammatory origin in the nasopharynx and contribute their part in diminishing the permeability of this canal. 3. In both cases their destruction is indicated.

In a somewhat careful review of the literature I have not found a case like the above. Complete atresia of the nasopharynx with atresia of the nose has been recorded as giving rise to great deformity of the face with impaired mental development. Escat in his work on diseases of the pharynx pictures two such cases. They are very rare. My patient did not get sufficient air through the nose on account of the membrane and the dryness of the mucous membrane of the pharynx was certainly due in part to mouth breathing. It is probable that the tinnitus and the suppuration in the middle ear were connected with the formation in the nasopharynx.

The proper treatment was undoubtedly the removal or the tearing through the abnormal tissue to give better nasal respiration.

919 N. Charles Street.

THE FLUOROSCOPE IN DIAGNOSIS OF ANEURISM.

G. R. GAGE, M.D.

AND

H. H. HEYLMUN, M. D.

HUTCHINSON, KAN.

History.—W. H., aged 29, married, gave a negative family history. For 12 or 13 years, until two months ago, his occupation had been that of a steam hammer driver. On an average of probably 5 times a day he would throw his weight on a heavy lever, alighting on the abdomen. He had never had any illness from the age of 14 to 24; he had been a hard drinker; was treated 8 years ago for specific trouble, which showed as a row of indurated ulcers, extending around the corona; this condition baffled his physicians for 10 months, but yielded immediately to the application of dry calomel. No suspicious symptom developed since.

Eight years ago he noticed pain in his left hip and leg, which rapidly became very severe, compelling him to walk with a cane for the next four years, though not preventing him from attending to his work in the machine shop. For the past four years the pain has been present more or less constantly, though not so severe as formerly, and not severe enough to necessitate the use of a cane. For the past year he has suffered from a heavy boring paroxysmal pain in the abdomen, which would sometimes be absent for a day or two, but most of the time present and getting progressively worse.

Appetite was fair; there was no trouble with digestion, no nausea and bowels were regular. There was some emaciation; patient was pale, expression indicated suffering.

Examination.—Examination of abdomen revealed pulse of 94, temperature normal, and marked condition of arteriosclerosis. There was tenderness over the great sacrosciatic notch. There was what appeared to be a spasm of the recti muscles; with head and knees elevated a tumor, hard and immovable, was made out just to the right of the umbilicus. The tumor was pulsating and seemed to possess that peculiar expansive pulsation indicative of aneurism. On auscultation a blowing sound was heard somewhat like that of a mitral regurgitation. This bruit almost entirely ceased after the patient had been in the recumbent position a few moments. Comparing the anterior tibial pulse with that of the radial, the former was found to be about one-third of a beat behind the latter. There was no swelling of the ankles or dilatation of the superficial veins of the abdomen, nothing to indicate interference with return circulation.

As a possible aid to diagnosis, the patient was placed in front of an *x*-ray tube requiring a 7 inch spark gap. By the aid of the fluoroscope a dark shadow about 3 inches across laterally was discerned at the site of the tumor. By close attention one could readily make out an expansion and contraction of this shadow corresponding with the pulse beat; this expanding and contracting shadow had very much the appearance of the heart as seen through the fluoroscope and immediately appealed to us as being a diagnostic procedure of great value in cases in which aneurism is suspected.

In this case the diagnosis of aneurism of the abdominal aorta was made and the family acquainted with all the facts of the case, also the possibility of a mistake in diagnosis which could be positively determined only by an exploratory incision.

Operation.—Consent of the patient and family was readily given and the patient prepared for operation. While under the anesthetic, and the abdominal wall relaxed, an elevation was seen at the location of the tumor. An incision was made through the right rectus muscle, directly over the most prominent point of the tumor, and after working gently through some slight adhesions, an aneurism half as large as a teacup was found. It appeared to be fusiform at its lower extremity, which was just above the bifurcation; the right side was lobular and extended fully an inch to the right of the median line. Owing to the fact that the patient took the anesthetic very poorly, no further exploration was made, and the wound was closed.

In this case there was a positive history of alcoholism and a probable history of specific trouble, either one of which may have been the cause of the arteriosclerosis. The continued bruising of the vessel at this particular point, no doubt, had to do with causing the aneurism.

The point in the case which seems of the most value to us, and the one to which we desire to call the attention of the profession, is that of the use of the fluoroscope. These patients are usually more or less emaciated and afford excellent subjects for *x*-ray work, and the expansive pulsation of the tumor is much more perceptible to the fluoroscope than it is to the finger tips.

Naming of Carbon Compounds.—In the *Pharmaceutical Review*, July, W. A. Puckner, Chicago, publishes a compilation "of terms, syllables, prefixes and endings commonly employed in the naming of carbon compounds," for the use of students in pharmacy and medicine, and for pharmacists and physicians. Chemical terms which are usually unintelligible to the average physician are explained in simple language, and the derivation is given.

SATURDAY, SEPTEMBER 1, 1906.

FEATURES OF LIFE INSURANCE EXAMINING WHICH DEMAND CORRECTION.

In the radical reformation which is taking place in some of the life insurance companies as the result of the recent investigations and the exposure of gross irregularities, it is to be hoped that the status of the medical examiner will be considered, the importance of his duties more keenly appreciated, and correction made of conditions which have sometimes made it difficult for the examiner to do his work without violating his sense of decency and self-respect. The abuses which we have in mind have grown up, for the most part, in connection with high-pressure methods of soliciting new business, arising from the intense competition among the companies and the eagerness to pile up a large surplus. It is evident for the last few years the agency department of many of the companies has been the dominant factor, and the insistent command has been "get new business," at whatever cost and at whatever sacrifice to the other interests of the company; "get new applications, even by force or fraud, if such be necessary." It is equally evident that such a course is not conducive to the best interests of the policyholders, who are the real owners—the stockholders of the company.

All this is of interest to the examiners because they have unwittingly been made parties to these methods in a variety of ways. Until recently in many companies the appointment of examiners was largely controlled by the agents and this power was often made use of to secure applications from physicians under the promises of appointment to an examinership. How detrimental this was to the interests of the other policyholders is well shown by a statement recently made by the medical director of one of the largest of the American companies. The death losses for a period of five years, during which the examiners were recommended by the general agents, were compared with the losses for a similar period immediately following a change to the plan of appointment entirely independent of the agency department. It was ascertained that the actual saving to the company through lessened mortality under the latter plan had been sufficient to pay the total expense of the medical department during that period, including all examination fees, salaries of medical officers and other expenses.

The interests of the agent, the placing of his risks and securing his commission are, in a sense, antagonized by the interests which the examiner is appointed to protect. The cordial relations which should exist between the examiner and the agent are not promoted by ignoring this fact, but by its frank recognition, and by the confidence of the agent that the physician is capable and honest and will always give his applicant a "square deal." It is essential to such pleasant relations, as well as to the efficiency of the examiner, that he should occupy an absolutely independent position in reference to the agent, being responsible directly and only to the medical department. Any arrangement which enables the agent in any way, directly or indirectly, to coerce the examiner is unfair to the physician and bad for the company. Such coercion is possible when two or three examiners occupy the same territory for one company, if the agents are permitted to take their examinations to the examiner of their choice. It is possible in such a case for the agents to take most or all of their cases to a favorite examiner, making his income from this source a large one, while the other examiner has little or no business. In such instances the examinations should be made independent of the agent either by having a chief examiner to whom all applications are submitted and who assigns them equitably, or by placing the examiners on a salary (usually objectionable on other grounds), or through a pooling of the examinations by the physicians themselves.

We shall have something more to say along these lines in subsequent issues.

CAISSON DISEASE.

It has been demonstrated by means of experiments on animals that the serious results to health which are frequently the accompaniment of the duties of professional divers and of those who work in caissons must be attributed to a too rapid rate of the process of decompression on return to the normal condition. Up to a few weeks ago the most reliable data with regard to the disease had been collected by M. Hersent, a French engineer. In 1894, at Bordeaux, he had carefully noted and discussed the influence of high air pressure on the human subject in the persons of three workmen who had voluntarily submitted themselves to the ordeal in the interests of science. These men were enclosed in a steel chamber, and the experiments were conducted under the observation of a commission composed of members of the Bordeaux Faculty of Medicine. The defects of M. Hersent's investigations lay in the fact that no scientific records could be taken on the spot, as would have been the case had a trained scientific experimenter been in the chamber.

Dr. Leonard Hill, F.R.S., and Mr. Greenwood, M.R.C.S., two Englishmen, have been recently engaged in personal experiments[1] of a like nature with the object in view of clearing up some obscure points. They caused to be constructed a large steel cylinder in which one or the other was shut. This had a capacity of 42.2 cubic feet, with a motor-driven pump for effecting compression and taps for decompression. It may be said that both the experimenters were in excellent physical condition at the commencement of the investigations. Drs. Hill and Greenwood underwent varying degrees of pressure in their cylinder, and each wrote a diary of his sensations. The highest pressure to which Dr. Hill was subjected was 75 pounds, while Mr. Greenwood underwent a pressure of no less than 90 pounds. Neither suffered from serious after effects, not even when the maximum pressure of the series was reached, one corresponding to a water depth of 210 feet. The point especially emphasized was the vital importance of a gradual decompression period. In fact, the authors assert that "the responsibility of those who allow short decompression periods is clear; every death or case of paralysis from air embolism must be set down to the negligence of the contractor." It is also pointed out that, during the process, it is essential to exercise well every muscle and joint of the body, and to change the posture frequently in order to maintain adequate capillary circulation.

---

[1] Proceedings of the Royal Society of London, February, 1906; Lancet, June 30, 1906.

The experimenters faithfully recorded the physiologic changes induced while under pressure in the chamber. It was noticed, among other effects, that at three atmospheres the vibratile movements of the tongue and lips practically ceased. All distinct sensations of pressure in the ears was relieved as soon as the pump ceased its strokes, and the pressure in the chamber became constant. The final conclusion arrived at was that an adult may be safely submitted to a total barometric pressure of at least seven atmospheres, provided that the precaution of making the period of decompression gradual be strictly observed.

There is probably more caisson work going on, as a rule, in the United States than in any portion of the globe. The danger attending the work was much in evidence during the construction of the last suspension bridge in New York, when several of the workers suffered severely from "caisson disease." The investigations of the English medical men are, therefore, valuable, and their advice as to the decompression period should be taken to heart by all large bridge builders in America.

MARITAL CONSANGUINITY AND DEFECTIVE CHILDREN.

There are not a few, even of physicians, who are apt to consider that the old-time ecclesiastical regulations forbidding the marriage of blood relatives, which have become the basis for most of our modern legislation on this subject, are founded on moral rather than on good physical grounds. There is a natural feeling of repugnance against the marriage of very near relatives, but there is an impression, now altogether too general, that cousins may marry with impunity. For those who entertain any such idea the report of the United States Census Bureau on the blind and the deaf, which has recently been published by the Government Printing Office, will provide material for very serious consideration. This report is written by Dr. Alexander Graham Bell, better known popularly as the inventor of the telephone, but who has a world-wide reputation as an expert of scientific thoroughness with regard to deafness and its causes and conditions.

Some years ago Dr. Bell succeeded in demonstrating that nearly three times as large a proportion of the deaf children born of parents who are cousins are congenitally deaf as of children born of parents who are not thus related. This average is confirmed by the statistics collected very carefully for the present census report, and statisticians in other countries have found practically the same proportion, occasionally even worse.

With regard to the blind the state of affairs as pictured by the census report is even more deterrent. Of the blind who were the offspring of consanguineous marriages, meaning that the parents were related as closely as cousins, proportionately 3.67 times as many are born blind as in the case of the blind who were children of those who were not so related. In the case of both the deaf and the blind the census figures show that 4.5 per cent. of all cases are the offspring of parents who are cousins. With regard to the blind, altogether some sixty thousand cases are analyzed, so that there would seem to be no doubt that the conclusions arrived at are amply justified and that the results obtained are not mere coincidences nor to be attributed to a narrow view of the question.

In discussing the statistics, Dr. Bell points out that the view of the situation obtained is likely to be better, instead of worse, than is actually justified by the real state of affairs. It can be readily understood that many persons, when questioned as to the consanguinity of parents, either refuse to answer or occasionally even prefer to deceive rather than to admit the possible influence of this fact in their condition. From not a few of the deaf and blind it has been impossible to obtain definite statements with regard to parental relationship. All such cases have been excluded from the statistics. It seems not unlikely that most of these cases were really examples of parental consanguinity, and they would make the expectation as to defective children even more appalling than it is. In not a few cases, as every physician knows, the consanguinity of parents is deliberately concealed from children whenever the surrounding circumstances (as, for instance, residence at a distance from other relatives) allows the subterfuge.

Already the number of defective children is so much on the increase from the stress and strain of large city life that every possible factor which adds to the probability of the reproduction of further unfortunates must be removed. Medical examinations of school children show that defects in the special senses are particularly frequent. If parental consanguinity can, as is proved by these statistics, add to the number of the totally blind and deaf, then it must be even more important as an element in the causation of such minor defects in the special senses which are serious handicaps in the battle for life. If this state of affairs is true for blindness and deafness, it can be concluded that it is also true for all the complex physical mechanisms which underlie the most important functions of human life. German statistics show that stutterers, for instance, are more common in the families of related parents than among the ordinary population. Various muscular weaknesses of a hereditary character must be placed in the same category.

It seems clear, then, that the marriage of cousins should be discouraged in every possible way. The possibilities of offspring being deformed or defective are already sufficiently appalling to make prospective parents uneasy. To increase the chances of such an unfortunate event by three or four times is enough of itself to give the most careless person pause. About one-half of the states in the Union have laws forbidding the marriage of cousins by blood and it would seem that their example should be followed by the other states.

THE DECREASE OF DRINKING AMONG PHYSICIANS.

A religious paper claims that drinking is on the increase among physicians, and in support of this statement it refers to a banquet that was given under the auspices of the staff of one of the hospitals of a large city west of the Mississippi River, at which, it was reported, only four of the fifty physicians present abstained from drinking. The report may be true, but we can not accept the conclusion it is quoted to support. We do not believe that drinking habits are on the increase among physicians. There are many who drink some and some who drink too much on occasions or even habitually, but we believe that there were many more of this kind a generation ago, and as the advocate of temperance the medical profession is much more to the fore at the present time than at any previous period. The statement is one of those unfortunate generalizations based on insufficient knowledge of the facts, and one which a religious journal, of all others, should be most careful to avoid.

THE CASE OF "DR." CARSON.

The *Independent*, a weekly journal published in Kansas City, is a good running mate for *Collier's Weekly* in the fearlessness with which it exposes frauds and fakes of all kinds. The newspapers of Kansas City have not yet reached that commendable state in which they exercise discrimination in the publication of objectionable advertising. This is particularly true so far as medical advertisements are concerned. Mr. George Creel, the editor of the *Independent*, has been giving considerable space to the exposure of the doings of quacks. In a recent issue he devotes some space to one "Dr." C. H. Carson, who poses as a "vital healer" and whose place of residence, where all the "cures" are effected, is known as the Temple of Health, or, as the *Independent* puts it, the Pimple of Wealth. The treatment employed by "Dr." Carson consists of the laying on of hands, blessing tissue paper to place on tumors in women's breasts, placing bits of torn paper in an envelope, with the warning that they must not be exposed to light, etc. It would appear that "Dr." Carson and his methods ought to be made the objects of a vigorous investigation by the State Board of Health. So far as we can learn, the "doctor" is not licensed to practice, and if he is not practicing medicine within the meaning of the medical-practice acts of Missouri and Kansas, thus relieving the State Board of Health of any responsibility in the case, the matter ought to be taken up in the interests of the people by the Medical Society of Kansas City. Meanwhile the *Independent* is to be congratulated on its courage. It deserves the support of medical men, as well as of the public.

ALCOHOL AS AN INTERNAL GERMICIDE.

A health commissioner of one of our great cities, according to the newspapers, recently uttered the rather rash advice to use whisky or alcoholic drinks to prevent typhoid in the existing unsafe condition of the city water. It is hardly possible that the advice was given seriously. It was probably merely a facetious suggestion inspired by the local atmosphere of the city hall, but it has been generally taken up by the newspapers and more or less seriously discussed. As an advice to the public in general it is about on a par with the ancient recipe for the cure of the toothache, to "let an omnibus run over your foot." We would not venture to say how much alcohol it requires to kill a bacillus, but it would take a rather unsafe quantity to neutralize any very thoroughly infected water. Alcohol may, in certain conditions, be a useful medicine, but it is rather unreliable as a prophylactic for most diseases.

Medical News

ILLINOIS.

New Sanitarium.—It is reported that Drs. Jeremiah H. Stealey and Carl F. Snyder will establish a modern sanitarium in Freeport.

To Enforce Laws.—The Board of Health of East St. Louis has instructed the Health Inspector to see that conductors of street cars enforce the laws regarding expectoration.

Personal.—Dr. and Mrs. Lyman Ware, Chicago, have returned after four months in Europe.——Dr. Albert H. Dollear, Jacksonville, has been appointed assistant physician of the Illinois Western Hospital for the Insane, Watertown.

Reform in Asylums.—The State Board of Charities, in its quarterly bulletin, states that as a result of its inquiries, the board feels that there is pressing need for a correlation of the energies of the state hospitals for the insane. No two institutions are alike, but in the majority of items of administration, standardization is necessary to elevate the institution to a high plane of efficiency and economy. The hospitals for the insane were found to be topheavy on the custodial side. The superintendents are burdened with business details which prevent them giving sufficient attention to the medical administration. For this reason, the hospitals are more like detention boarding-houses than places for the modern treatment of hopeful cases, and the industrial re-education of chronic types.

Chicago.

Typhoid Fever.—No increase in typhoid fever was reported during the week except in Rogers Park and Maywood. In Rogers Park the cause was attributed to the use of well water, which has been found to contain large numbers of the colon bacillus, and in Maywood the interference with sewage disposal pending the construction of a new sewer, is said to be the cause of the condition.

Deaths of the Week.—The total deaths from all causes in Chicago for the week ended August 25, was 589, 58 more than for the preceding week, and 12 more than for the corresponding week of 1905. The mortality was equivalent to an annual death rate of 14.91 per 1,000. Acute intestinal diseases caused 149 deaths; consumption, 58; heart diseases, 37;; pneumonia, 34; cancer, 32; Bright's disease, 31; and violence, other than suicide, 38.

Heat and Humidity.—During the week ended August 25, 9 deaths were reported as caused directly by sunstroke, but this represents only partially the effect of the prolonged high temperature and excessive humidity. Of the increase of 58 deaths, as compared with the previous week, cancer and heart disease contributed each 12 and acute intestinal diseases 24. It is probable that in these cases the fatal termination was the result of the prevalent weather conditions.

INDIANA.

Added to Faculty.—Dr. Lemenuel W. Famulener, for three years research fellow in pharmacology under Dr. Cushny at the University of Michigan, and for one year a worker with Dr. Mansen in the Statens Serum Institute at Copenhagen, has been appointed assistant professor in pathology at the Indiana University.

MARYLAND.

Baltimore.

College Building to Be Sold.—It is reported that the Baltimore University building on Bard Street will be sold and the institution closed.

Increase of Typhoid.—The usual autumn increase of typhoid is manifest, fifty-five cases of typhoid having been reported last week and eleven deaths.

Acquitted.—Dr. John W. C. Cuddy, charged with causing death by an illegal operation, has been discharged by the grand jury, no evidence being found against him.

Physicians Injured.—Dr. J. Ridgeway Andre, an aged physician, still in practice, suffered injuries, August 21, by a breakdown of his carriage and consequent runaway.

Plan for Extermination of Mosquitoes.—Dr. Bosley, health commissioner, proposes a plan for the extermination of mosquitoes, which includes fines on tenants or property owners who allow water to stagnate in their yards, and makes health wardens and police officers responsible for the conditions and for failure to report violations of the laws. The present municipal agencies are to be employed in this work, so that the plan involves no extra expense to the taxpayers.

Vacation Time.—Dr. Ira Remsen is at Prout's Neck, Maine. ——Dr. George Reuling has returned from Narragansett.—— Dr. William H. Howell is at Chebeague Island, Maine.——Dr. James D. Iglehart is at Saranac.——Dr. R. Martin Bruns is at Allenhurst, N. J.——Drs. George W. Mitchell, Robert Hoffmann and Albert Colby are in Paris.——Dr. Amanda Taylor-Norris is at Rehoboth Beach, Del.——Dr. Joseph Blum is at Ocean City, Md.——Dr. William Whitridge is in Rhode Island.——Dr. Howard Kelly is traveling in Europe.——Dr. T. Chew Worthington is taking a trip to Niagara Falls and the Thousand Islands.

MINNESOTA.

Personal.—Dr. F. Dale Smith, Oronoco, was thrown from his buggy July 26, and sustained a fracture of the leg.——Dr. John W. Andrews, Mankato, is taking a trip to Southern Oregon.

Bly Imprisoned.—Dr. Theron H. Bly, Minneapolis, convicted of performing a criminal operation, and sentenced to imprisonment for three years and a half, began serving his sentence in the state penitentiary, Stillwater, August 11.

Scarlet Fever in Eveleth.—The Commissioner of Health of Eveleth announces that there have been 24 cases of scarlet fever in the city, but that the outbreak has been mild and well under control, and that the number of cases has decreased since July 10. Since August 1 there have been not more than nine cases at any time and there are but four existing now.

Bemidji Man Said Not to Be a Leper.—Arndt Reton, classed by the Bemidji physicians as a leper and placed under quarantine far away from the city, made his escape and went to Cass Lake, where he was examined by the physicians, who claim that he is not afflicted with the disease. The two toes which he had lost were amputated as the result of frozen feet two years ago.

Care of Veterans.—Under the direction of Dr. Charles A. McCollom, Minneapolis, chairman of the committee on health and comfort, the physicians of the city organized for special duty the week of the encampment. The entire city was divided into sections and a force of 150 physicians assigned on duty in this division.. In cases where public school buildings were used for dormitories a special physician had been placed in charge of each. In all notices sent out, the lodging places and the name and address of the physician in charge of the district was given. Headquarters were opened in the old city hall building for the entire encampment, and two ambulances were secured. Nine stations were established along the line of march and the results showed the great care exercised in the organization of the medical service.

MISSOURI.

Fined for Selling Cocain.—A clerk at the Franklin Pharmacy, St. Louis, on August 14, was fined $20 and costs on the charge of selling cocain to two women. This is the first prosecution under the law for selling cocain without prescriptions therefor.

Hospital Staff Chosen.—At a meeting of the Home Missionary Society of the Methodist Episcopal Church of Springfield, the following staff of physicians for the new Burge Deaconess Hospital was elected: Drs. John C. Matthews, William C. James, George W. Barnes, John W. Williams and John P. Ralston. The attending staff are Drs. Francis E. Ross, Jonathan E. Tefft and William M. Smith.

Cancer Deaths Increasing.—The statistics of the St. Louis Health Department show that cancer is on the increase in the city, notwithstanding the decrease in the total number of deaths. In the year 1903-04, 11,486 deaths occurred, 391 of which were from cancer; in 1904-05, 11,364 deaths, of which 398 were from cancer, and in 1905-06, with only 9,833 deaths, 438 deaths are reported to be due to the disease.

Tenement Board Named.—The mayor of Kansas City has sent to the council an ordinance naming a tenement board of seven, of which Dr. Orville H. Dove is the medical member, together with a communication pointing out the necessity of such a commission. The duty of this board is to investigate the tenements of the city, to report to the Board of Health the conditions existing among the city's poor, and to recommend such ways and means for the improvement of the situation as are thought necessary and practical.

NEW YORK.

Bequest.—By the will of the late Theodore S. Hubbard, Geneva, a bequest of $500 is made to the Geneva City Hospital.

Diphtheria in Watertown.—During July there were 17 cases of diphtheria reported in Watertown. Despite the investigations of the Board of Health no cause could be determined for the disease.

Typhoid Fever.—Corning reported 152 cases of typhoid fever, due in every instance to the use of water from wells. The city water has been analyzed and has been found to be free from all disease germs.——On account of the prevalence of typhoid fever in and around Baldwinsville, Dr. F. P. Sinclair, Lysander, has been authorized by the Board of Health to make a thorough examination of the camps and cottages in the vicinity.

Buffalo.

Hospital Acquires Land.—The Children's Hospital, Buffalo, has acquired a tract of land adjoining the hospital for the purpose of building an extension to the institution.

Personal.—Dr. W. Harry Glenny is at East River, Conn.—— Dr. Stephen Y. Howell has returned from the sea shore. Dr. Reuben M. Root from the Muskoka Lakes and Dr. Frank W. Love from Lake Bonaparte.——Dr. Matthew D. Mann will go on a hunting trip to Wyoming and Colorado early in September.——Dr. F. Park Lewis will return from Europe shortly. ——Drs. Irving W. Potter and Roland O. Meisenbach were recently elected on the staff of the German Hospital.——Dr. Harry Mead has been at the Thousand Islands.

New York City.

Trachoma Increases.—It is stated that ten sufferers from this disease have been deported daily from Ellis Island during the last two months, a much larger number than usual.

Personal.—Dr. John A. Billings arrived on the *Baltic*, August 22.——Dr. Henry F. Owsley, Flushing, has sailed for Europe.——Dr. Mary G. Patten is visiting in southern California.

Filtration in Sight.—Bids have been asked for an experimental plant for Jerome Park reservoir. This experimental plant is merely the forerunner of a great filtration plant that will be erected after the experimental plant shows just what the ingredients of New York water are.

Fresh Air Camp.—A fresh air camp has been established by the Association for Improving the Condition of the Poor and is in operation at the foot of Sixty-second Street, for the treatment of infants under 18 months of age. It has accommodations for fifty and every cot is occupied.

Typhoid in Brooklyn.—Since August 1, 76 cases of typhoid fever have been reported to the health authorities of Brooklyn. No definite cause has been found for the unusual prevalence of the disease, but the general belief is that it is due to the inferior quality of the drinking water supplied from the Ridgewood reservoir.

For Tuberculosis Hospital.—Plans have been filed by the Department of Charities for a new tuberculosis hospital to be erected in the Borough of Richmond on land recently purchased near the present City Farm. The buildings will be eight in number, each four stories high, 80 by 137 feet, on the ground plan, and will cost $800,000. This institution will be called the Sea-Side Hospital.

Opposes New Building for Hospital.—Comptroller Metz opposes for the present the erection of new contagious-disease pavilions in connection with the Kings County Hospital. The citizens of the neighborhood are endeavoring to have this hospital removed to a less crowded neighborhood. The Board of Health will ask for the appropriation of $32,000 for the contagious pavilions, and if no better location is available, the extension to the present hospital will be undertaken.

Error in Certificate.—Dr. Simon M. Roth, charged with falsely filling in a death certificate, was acquitted in the Yorkville police court, August 9. His certificate read that the decedent, Lena Schultz, 38 years old, died at 233 East Seventy-eighth Street, but in reality the woman's name was Green, she was 18 years old and died at 138 East Seventy-eighth Street, the residence of a midwife. Under the new law it is not necessary to certify as to the direct as well as the indirect cause of death.

Vital Statistics for Second Quarter.—The report of the Health Department for the quarter ended June 30 shows 25,692 births and 18.928 deaths, equivalent to an annual death rate of 18.29 per 1,000. There were 12,467 marriages, a gain of 1,584 over the same period of last year. Pulmonary tuberculosis claimed 2,319 victims, tubercular meningitis 221 and other forms of tuberculosis 113. There were 1.527 deaths from pneumonia and 1,223 from violence. Of children under 5 years of age there were 6,237 deaths, of which 801 were due to summer complaint. Of the deaths 8,967 occurred in the tenements.

Contagious Disease.—There were reported to the sanitary bureau for the week ended August 11, 371 cases of tuberculosis, with 173 deaths; 128 cases of diphtheria, with 16 deaths; 125 cases of measles, with 4 deaths; 116 cases of typhoid fever, with 16 deaths; 56 cases of whooping cough, with 11 deaths; 9 cases of cerebrospinal meningitis, with 10 deaths; 53 cases of scarlet fever, 8 cases of varicella and 1 case of smallpox; a total of 867 cases with 230 deaths. There were reported to the sanitary bureau for the week ending August 18, 376 cases of tuberculosis, with 176 deaths; 151 cases of diphtheria, with 20 deaths; 113 cases of typhoid fever, with 10 deaths; 67 cases of measles, with 6 deaths; 51 cases of whooping cough, with 18 deaths; 32 cases of scarlet fever, with 2 deaths; 9 cases of cerebrospinal meningitis, with 4 deaths; 17 cases of varicella and 1 case of smallpox; a total of 817 cases, with 236 deaths.

OHIO.

Personal.—Dr. Max Heidingsfeld, Cincinnati, has gone to Berne, Switzerland, to attend the meeting of the Dermatological Congress.——Dr. David P. Shie, Orrville, who is critically ill with hepatitis, is improving and believed to be on the way to recovery.

Free Antitoxin.—The State Board of Health has made an arrangement whereby it acts as a distributing agency to supply diphtheria antitoxin to local boards of health for use where it might otherwise be unavailable on account of poverty. The antitoxin is the property of the manufacturer and is to be paid for by the local boards of health as required.

Typhoid Fever at Cincinnati.—Drs. Martin Lewis and Dudley Palmer of the house staff of the City Hospital have gathered some interesting data regarding the epidemic of typhoid fever. Between April 1 and August 13, 230 cases of the disease were treated at the hospital. The cases were located between Liberty Street and Walnut Street east to the bottoms, and again on Central Avenue from the city hall to Liberty Street and south of McMicken Avenue and west of Eggleston. This territory receives its water supply from the Third Street reservoir. They find typhoid most prevalent among the Hungarians and other recent immigrants who have little or no knowledge of the laws of hygiene.

PENNSYLVANIA.

Operated On for Appendicitis.—Dr. Calvin H. Elliot, resident physician in the Insane Asylum at Harrisburg, has been operated on for appendicitis in the Medico-Chirurgical Hospital, Philadelphia.

Sanitarium Burned.—The main building of the Grand View Sanitarium, an institution for the treatment of consumptives near Oil City, was burned August 19. The loss is $5,000, partly covered by insurance. The patients, 196 in number, all escaped uninjured.

Dr. Mackey's Death.—In the notice of the death of Dr. Charles D. Mackey, Montrose, which appeared in The Journal of August 18, page 528, it was stated that he was a member of the Susquehanna County Medical Society from 1888 to 1901. The secretary of the society writes that this is incorrect, as at no time was Dr. Mackey a member of the society.

Hydrophobia Prevalent.—It is reported by Dr. Aime Leteve, who is in charge of the Magee Pathological Institute, Pittsburg, that there are a large number of cases of hydrophobia in Western Pennsylvania, Ohio, West Virginia and Maryland. As many as thirty cases have been under Professor Leteve's care at one time during the last two months, and at present there are sixteen under prophylactic treatment at the institute.

Food Commissioner Victorious.—A notable victory in the administration of the pure-food laws of the state has been achieved by Dr. B. H. Warren, dairy and food commissioner. The commissioner's chemists having discovered sulphur dioxid in much of the candy examined, charges were brought against the manufacturers and dealers. The manufacturers stated that the glucose containing this preparation (which was used for bleaching) was supplied solely by the glucose trust, a subsidiary of the Standard Oil Company. The commissioner had included the representatives of the trust among those against whom charges had been made, and the trust, seeing it was useless to fight the state law and the commissioner, asked for a conference. At this conference the trust's attorney admitted that the charges were true and promised to settle all fines against the manufacturers, and, moreover, to withdraw all bleached glucose from the markets of Pennsylvania and from the markets of the United States. In this manner the commissioner has drawn the attention of the entire country to the fact that harmful substances are universally used in the manufacture of glucose candy, and by the enforcement of the pure-food laws has eliminated for the future this danger to the public health.

Report of Food Commissioner.—Dr. B. H. Warren, state dairy and food commissioner, in his report for 1905 states that the milk supply of Philadelphia "has no superior, if equal, in any city in the United States." Many hundreds of samples of milk and cream were collected for examination, with most satisfactory results. The crusade in the interests of pure food has been expensive, but has been the means of saving many lives in other sections of the state as well as in Philadelphia. A smaller percentage of adulterated, preserved or impure articles of food and of milk in particular is sold. The number of prosecutions ordered during the year is much less than during the preceding years. The following summary of the total number of suits ordered by the commissioner shows the decrease in figures: In 1903, 1,800; 1904, 1,517, and 1905, 1,085, a total of 4.402. The report says:

> The decreasing figures form their own commentary. The continued violation of the oleomargarine law was productive of the next to the largest number of suits ordered in 1905, namely 187, while thirty defendants were charged with violating the renovated butter law. The sale of chemically preserved meat, sausage, etc., resulted in the ordering of over 200 prosecutions. Jellies, jams and preserves were found illegal in 144 cases, while Marachino cherries produced

fifty-three unfavorable chemists' reports. Eighty-three samples of catsup were found to be illegal, while prosecutions were directed against fifty-two dealers who sold Worcestershire and other sauces containing forbidden chemicals. In strange contrast with previous reports, only forty-seven samples of milk and cream proved unlawful.

Philadelphia.

Public Baths.—The total number of bathers at the city bath-houses last week reached 605,066. Of this number, 131,156 were men, 4,757 women, 449,982 boys and 19,171 girls.

Bequests.—By the will of the late Ellen Summers $2,000 is to be divided equally among the West Philadelphia Branch of the Little Sisters of the Poor, St. John's Orphan Asylum for Homeless Boys and the House of the Good Shepherd.

Trachoma in Immigrants.—In fifty out of the 340 steerage passengers who arrived on the American Line steamer *Westernland*, August 20, traces of trachoma were found. It is expected that about one-fifth of this number will be deported.

New Officials for Health Bureau.—Director W. M. Late Coplin, of the Department of Public Health and Charities, has made the following appointments: Dr. Augustus H. Clagett, assistant medical inspector; John H. Lehman, nuisance inspector, and Thomas H. Nelson, milk inspector.

Personal.—Dr. Samuel W. Morton is slowly recovering from a severe attack of appendicitis.——Dr. Edward P. Davis sailed for Europe, August 25.——Dr. James P. Hutchinson, who has been spending the summer abroad, will return home the end of September.——Dr. J. C. McCracken, who went to China last December to help found a medical school and hospital in Canton under the auspices of the University of Pennsylvania, has returned to this country. He will assist in the dedication of the new University Settlement House in this city and will then deliver a series of lectures to raise funds for the Canton Medical School.

Health Report.—The total number of deaths for the week numbered 481, a decrease of 17 from those reported last week and an increase of 44 over the number reported in the corresponding week of last year. The principal causes of death were as follows: Typhoid fever, 12; whooping-cough, 17; scarlet fever, 3; diphtheria, 4; tuberculosis, 58; cancer, 22; apoplexy, 15; heart disease, 25; acute respiratory diseases, 24; diarrhea and enteritis, 90; appendicitis, 4; Bright's disease, 43; congenital debility, 18; senility, 4; suicide, 6; traumata, 8; accidents, 9, and marasmus, 9. There were 149 cases of contagious disease reported, with 19 deaths, as compared with 189 cases and 19 deaths reported for last week.

SOUTH DAKOTA.

Epidemic of Typhoid.—More than 100 persons are reported to be seriously ill with typhoid fever at Bristol, Andover and Webster, and five deaths are reported.

New Hospital at Yankton.—A number of Yankton businessmen held a meeting August 3, with Bishop O'Gorman at the Sacred Heart Hospital and reported progress on the new hospital project.——The Good Samaritan Association has been incorporated with a charter in perpetuity. Money for the erection of the hospital is to be secured through the issuance of 5 per cent. bonds, of which $50,000 worth are to be issued at once, redeemable in five, ten, fifteen and twenty years. In 1927 the hospital is to be turned over to the Benedictine Sisters.

TENNESSEE.

Health Crusade.—The Humboldt Medical Society has prepared a pamphlet on the laws of health which contains a series of articles on hygiene and sanitation for use in the city schools. A copy of this pamphlet is ordered to be placed in the book of every child attending school.

New Building for Academy.—The members of the Nashville Academy of Medicine at its meeting August 15, subscribed about $8,000 toward a new building to be used as a permanent home for the organization. About $20,000 is needed for this purpose.

Personal.—Dr. N. F. Raines, Memphis, has been appointed president of the Shelby County Board of Health.——Mr. Laurent Brown has been appointed lecturer of medical jurisprudence in the Medical Department of the University of Tennessee, Nashville.——Dr. George St. John, Knoxville, has been appointed physician at Bushey Mountain prison.——Dr. Henry J. Kelso, Knoxville, was thrown from his buggy August 4 and sustained a fracture of the leg below the knee.——Dr. Louis Leroy, Nashville, state bacteriologist, has accepted the chair of principles and practice of medicine in the College of Physicians and Surgeons, Memphis.

TEXAS.

Personal.—Dr. Nathaniel Cass, Cameron, who was operated on for appendicitis July 29, has recovered from the operation, but is now suffering from pneumonia.——Drs. Henry B. Decherd, William E. Howard, Scurry L. Terrell, Albert Wilkinson, Robert S. Yancey and John O. McReynolds, have been appointed medical inspectors of the Dallas Board of Education; Drs. Edwin J. Reeves, I. S. Kahn and George W. B. Swain have been appointed as an advisory board and Dr. Frank J. Hall has been appointed to act in conjunction with the advisory board.

District Society Meets.—At a meeting of the Central Texas District Medical Association, Dr. I. Newton Suttle, Corsicana, was elected chairman, and Dr. James W. Miller, Hillsboro, secretary of the section on surgery; Dr. Jesse B. Shelmire, Dallas, chairman, and J. Walter Torbett, Marlin, secretary of the section on practice of medicine; Dr. Leonard Keplinger, Waxahachie, chairman, and Dr. Burt L. Scott, Waco, secretary of the section on eye, ear, nose and throat and Dr. Oliver J. Halbert, Waco, chairman, and W. L. Crosthwait, Holland, secretary of the section on obstetrics and gynecology. Waco was selected as the next place of meeting.

VIRGINIA.

Punished for Selling Cocain.—James Hill, colored, Richmond, has been sentenced to serve a term of imprisonment of one year for selling cocain.

Personal.—Dr. Anna Moon Randolph, Newport News, is suffering from septicemia, resulting from an operation wound. ——Dr. Ernest Woolfolk, Thornhill, is ill and is undergoing treatment at the Memorial Hospital, Richmond.

Election.—At the annual meeting of the Augusta County Medical Society held in Staunton, August 8, the following officers were elected: Dr. John W. Freed, Hermitage, president; Drs. J. C. Alexander, Mount Solon; Walter S. Whitmore, Mount Sidney, and William C. Roller, Mint Spring, vice-presidents; Dr. Thomas M. Parkins, Staunton, treasurer, and Dr. Marshall J. Payne, Staunton, secretary.

WASHINGTON.

Typhoid Fever Diminishing.—The health officer of North Yakima, in his report for July, says that less than 12 cases of typhoid fever have been reported to him since last April, whereas, during the month of July, 1905, 54 cases were on record; and he believes the city to be in excellent sanitary condition.

License Revoked.—An order of the State Board of Medical Examiners has been filed in the office of the County Clerk of King County revoking the license of James Stewart of Seattle for unprofessional and dishonorable conduct. Stewart was charged with having attempted to bribe a member of the board with $600 to procure a set of the questions to be propounded at the examination. He was convicted in July, 1902, and appealed to the Supreme Court, which a year later affirmed the decision of the lower court.

WEST VIRGINIA.

Personal.—Dr. John G. Pettit, Clay, has been elected assistant at the West Virginia Hospital for the Insane, Weston.——Dr. George W. Daniels, Gerrardstown, was nearly stung to death by a swarm of infuriated bees a short time ago. He is now out of danger.——Dr. Charles B. Williams, Philippi, is ill with typhoid fever.

Poison Regulations.—An ordinance recently enacted by the city council of Charleston provides that no person shall sell except to dealers any poisonous drug or substance except when prescribed by a physician or when the purchaser has first been furnished with a written permit from the board of health. The enforcement of this ordinance is being strenuously opposed, it is said, by the druggists, who claim that it prohibits the sale of disinfectants and fungicides and the common household liniments, and is in conflict with the state law. At a meet held July 7 they resented the report that their opposition to the measure was due to a desire to profit from the sale of narcotics.

GENERAL.

Electrotherapeutists To Meet.—The sixteenth annual meeting of the American Electrotherapeutic Association will be held at the College of Physicians, Philadelphia, Sept. 18-20, 1906. Transportation is to be on the certificate plan at the rate of a fare and a third. The headquarters will be at the Hotel

Flanders, Fifteenth and Walnut streets. Dr. G. Betton Massey, 903 Professional Building, Philadelphia, is chairman of the committee of arrangements.

Negro Medical Association.—The eighth annual meeting of the National Medical Association of Negro Physicians and Surgeons of the United States was held in Philadelphia August 21-23. The association has a membership of over 2,000, and more than 500 delegates were present. The following officers were elected: Dr. Nathan F. Mossell, Philadelphia, president; Dr. George W. Cabannis, Washington, vice-president; Dr. John A. Kenney, Tuskegee, Ala., secretary; Dr. A. Wilberforce Williams, Chicago, treasurer; and Dr. Peter A. Johnson, New York City, chairman of the executive committee. The next meeting will be held in Baltimore in August, 1907.

Southern Tri-State Society to Meet.—The eighteenth annual meeting of the Tri-State Medical Society of Alabama, Georgia, and Tennessee will be held at Chattanooga, Tenn., Oct. 2-4, 1906. Reduced rates have been granted for Alabama, Georgia, Tennessee, Mississippi, Louisiana and Florida. The preliminary program includes an excellent list of papers from leading medical men of the south. As mentioned elsewhere, strong pressure will be brought to bear to convert this organization into a branch of the American Medical Association, the Association of the Southeastern States. Further information and places on the program may be obtained from the secretary, Dr. Raymond Wallace, Chattanooga, Tenn.

Health Report of the Isthmus for July.—In his report for July, Colonel Gorgas states that it is now eight months since a case of yellow fever occurred in Panama. During the month there were thirty-three cases of smallpox at Colon, with one death. The disease was introduced in the person of a child from Cartagena. With one or two exceptions the cases all came from one focus. The last case was reported July 29, and from that date till August 17 (the date of the report) no new cases had been discovered. Colonel Gorgas believes that the outbreak has been controlled and states that its prompt extinction was due to the energetic efforts of Dr. Wheeler, the health officer, and those who assisted him. The small death rate was due to the care given the sick by the superintendent of Colon Hospital and the officers under him. Among the 28,000 employés there were 151 deaths. Of these, 13 were among the 5,000 whites and 138 among the 23,000 blacks, giving the blacks more than double the death rate of the whites. Pneumonia caused the largest number of deaths; the next disease in point of mortality was malaria. In referring to the published reports that the death rate among the negroes is due to too much sanitation, Colonel Gorgas states that in his opinion this statement is erroneous. The obvious cause for the large death rate, he says, is seen in the very bad sanitation of their lives. They seldom possess a change of clothing, and when they reach home in the evening their clothes are soaked. They go to bed, sleep soundly, and as the air gets cold the men become thoroughly chilled. In general, the men feed themselves, and as they are improvident they do not give themselves nearly enough food. This, Colonel Gorgas believes, is sufficient to account for the prevalence of pneumonia among the negroes. The Canal Commission, he states, is endeavoring to remedy these faults, and when corrective measures have been put into effect the mortality from this cause will decrease.

CANADA.

Congress of French-Speaking Physicians of America.—The fourth congress of the French-speaking physicians of North America will be held at Quebec in June, 1908, on the occasion of the celebration of the three hundreth anniversary of the founding of Quebec by Samuel de Champlain in 1608. The congress will be presided over by Dr. A. Simard, with H. Hervieux as vice-president; Lanoix, vice-president for the United States, and Siroix, vice-president for the rural districts; A. Paquet, secretary general, and F. X. Dorion, one of the governors of the College of Physicians and Surgeons, the treasurer. The third congress recently closed its sessions at Trois-Rivières with an attendance of about 300, and more than 120 scientific communications on the program. Dr. Normand presided and Dr. C. Deblois proved an able secretary. A handsome medal was presented to the congress on behalf of the scientific societies of France, some of which were represented by special delegates. H. Triboulet was the official delegate of the French government and R. Proust of the University of France, while A. Loir represented a French scientific society. J. Ahern's communication on "Chorio-epithelioma" is given in full in the *Bulletin Médical de Quebec* for July. He describes 3 cases. The patients were 19, 44 and 30 years old. Cough and blood spitting were prominent symptoms in these cases. All the patients had had from 2 to 12 pregnancies, some of them terminating in abortion or premature delivery. The third patient had passed through 5 pregnancies and one recent abortion at four months, and when first seen was coughing and spitting blood, with much icterus and much weakness and emaciation. The case was diagnosed as chorioepithelioma with metastases in vagina, liver and lungs, but no autopsy was allowed. No operation was attempted and the patient succumbed in ten days. There was no history of a preceding mole in this case, as in the 2 others. Laurendeau of Brandon reported a case in which he had performed "extramedian symphyseotomy," hebotomy or pubiotomy as the operation for enlarging the pelvis by lateral section of the pubis is variously denominated. It was the first operation of the kind done in Canada, and proved eminently successful.

FOREIGN.

New Hospital for Belfast.—The new fever hospital for Belfast was formally opened August 2. This is said to be one of the best designed and equipped of its kind in the world.

Proposed Restriction of Marriage in Roumania.—The *Deutsche med. Wochschr.* refers to a decree whose adoption is now being discussed in Roumania, to prohibit marriage to persons suffering from incurable syphilis, pulmonary phthisis or epilepsy.

Smallpox in Central America.—Acting Assistant-Surgeon Layton reports that smallpox exists in Bluefields. Passengers leaving for Mobile have been vaccinated. The local governor assured Dr. Layton that he would appoint a board of health to take full charge of the situation. The situation is a serious one and local conditions all favor the rapid spread of the disease.

Collective Research on Appendicitis in Europe.—The Paris Académie de Médecine and the Berlin Verein für innere Medecin have each been devoting several sessions to a discussion of questions regarding appendicitis. Statistics show that the number of cases and the mortality from appendicitis are increasing in continental Europe. The German imperial authorities have now appointed a committee to undertake a collective investigation on the subject. It consists of eight members, the majority members of the Berlin society mentioned above.

Eighth International Congress of Otology.—This congress was to have been held at Budapest in 1908, but it has been postponed one year. This has been done because the next international medical congress is to be held at Budapest in 1909, and it has ben arranged that the congress of otology will convene as a special section for otology in the international medical congress. It will retain its autonomy, however, and be called the Eighth International Congress of Otology, as above. Prof. J. Böke of Budapest will preside, while Dr. S. Szenes is secretary general and Dr. E. Vali, treasurer.

International Tuberculosis Centralblatt.—Prof. L. Brauer of Marburg has been publishing for some time the *Beiträge z. Klinik d. Tuberkulose*, which is now in its fifth volume. He has recently commenced the publication of what he calls the *Internationales Centralblatt f. d. gesamte Tuberkulose-Literatur*. Both of the periodicals are issued by A. Stuber's Verlag, Würzburg. The *Beiträge* appear irregularly, from 3 to 5 numbers forming a volume, the price of which is 16 marks, or about $4. The *Centralblatt* is issued monthly, and the annual subscription is 8 marks, $2. O. de la Camp and G. Schröder are also interested in the publication, while the *Beiträge* has a long list of collaborators, including Schwalbe, Völker and Vulpius.

Responsibility of Hospital for Suicide of Patient.—A hospital maintained by the sisters of charity at Berlin has recently been sued for damages by the relatives of a man who jumped out of a window while delirious in pneumonia. The plaintiff stated that she had sent her husband to the hospital so that he could have better supervision than at home, but he had been left alone and he seized the opportunity to commit suicide. She claimed that the suicide could not have occurred if he had been properly watched. The hospital authorities said that close supervision all the time was impossible for the limited nursing force of the hospital, and that they had no funds to increase the nursing force. The judge held the nurse in charge of the case at the time responsible for the man's death and imposed the fine asked. It was a charity case.

The Professorship of Physiology at Glasgow University.—King Edward has appointed Dr. Diarmid Noel Paton regius professor of physiology at Glasgow University to succeed Dr. J. G. McKendrick. Dr. Paton is the son of the late Sir J. Noel

Paton, the well-known artist. *The Medical Press* states that Dr. Paton has been engaged for many years in teaching physiology in the extramural school in Edinburgh, while his position as superintendent of the laboratory of the Royal College of Physicians has proved his capacity both for carrying out original research and for inciting others to do the same. He is well-known as a distinguished physiologist, especially through his studies in dietetics and on the functions of the ductless glands; while he has also published a number of valuable researches in connection with the life-history of the salmon. Dr. Paton has been a most popular teacher in Edinburgh, the *Press* continues, and his influence for good and public spiritedness have made themselves felt in all matters connected with medical education. His training, though in the main physiologic, has brought him so much in contact with clinicians that in teaching he always emphasized the practical rather than the purely scientific aspect of physiologiy; he has never forgotten, as some physiologists are apt to do, that his pupils are going to be physicians, not physiologists.

Health of India.—Acting Assistant-Surgeon Eakins in *Public Health Reports*, states that the mortality in India from cholera is the highest recorded since 1901. The deaths from this disease number 146,339, giving a ratio of 2.93 per mille., against 1.63 in 1904, and 2.77, the quinquennial average. The mortality from plague in 1905 was the highest on record since the outbreak in 1898, the total number of deaths being 126,084, against 75,433 in the previous year, and 58,255, the average of the last quinquennium. The period of greatest prevalence was, as usual, from January to April, but the climax was reached in March, in which month alone 40,090 deaths from plague were reported. Twenty-seven districts were more or less affected by the disease, the districts which suffered most being Saran, Patna, Gya, Shahabad, Monghyr, and Calcutta. During the year rat extermination was carried on in many parts of the province, but notably in the Giridih coal fields and in Bihar. As an example of the efficacy of rat extermination the sanitary commissioner cites the instance of Jagadispur in the Shahabad district. The operations were carried on there very thoroughly, and though there was a good deal of the disease in Shahabad, Jagadispur itself enjoyed complete immunity despite the fact that a very large number of the people from other badly infected localities came to reside there. The arrangements to keep up the campaign for at least another twelve months are complete, and if, as is not impossible, a virulent and widespread epidemic occurs next winter, the places where rat extermination has been carried on will have an opportunity of demonstrating conclusively the practical results of this method of protection. During the year, 1.544 plague inoculations were performed. A total of 1,214,487 deaths was reported from "fever," the death rate from this cause representing a ratio of 24.34 against 20.49 per mille. in the preceding year, and accounting for 63.17 per cent. of the total deaths registered from different causes during 1905. Antimalarial measures, which, aimed at the destruction of mosquitoes, were tried at *Berhampore and Balasore*, and though it can not be claimed that they have as yet yielded great results, they caused a considerable reduction in the number of mosquitces and paved the way for more complete operations. Considerable activity was displayed by many municipalities in the administration of the various branches of sanitation. Inquiries were made during the year to ascertain whether filtration through sand and application of sulphate of copper rendered the effluent from septic tank installations bacteriologically pure. The net result of the experiments was to show that these methods. either separately or in combination, are capable of purifying the effluent, but that in practice they are likely to prove difficult in proportion to the amount of impurity in the material to be treated; and it was considered doubtful whether they would be practicable in the case of effluents of a high degree of impurity except as adjuncts to other methods of treatment. Sterilization of the effluent was then attempted by means of chlorinated lime. The experiment proved successful, and it was found that an addition of this material equivalent to 5 grains for each gallon of effluent rendered the fluid virtually sterile. The sanitary commissioner reports that septic-tank latrines are an entire success when used for communities such as mills, large schools. railway workshops, and the like. and he is now considering whether or not they can be adapted to municipal towns. He will be asked to submit a report embodying the results of his experiments. The sanitary commissioner has also made a number of suggestions for the adoption in municipalities of the septic-tank method as a

Pharmacology

Somnos.

Under the caption "The Chemistry of Chloræthanal"* the following has appeared in some of the drug journals for August:

An abstract of papers from *The Journal of the Illinois Medical Society* for February 14, 1906, seems to be going the rounds of the pharmaceutical and medical press. It contains among other papers one by Prof. Julius Stieglitz, Ph.D., entitled "The Problem of the Synthetic Chemical Compound," read at the "Symposium on Proprietaries" of the Illinois Medical Society. In reference to one of the products of our house the author says: "It bears in its description the statement that it is a compound of chloræthanal with a higher polyatomic alcohol, which is true. To a chemist. that spells at once chloral combined with glycerin. What physician who would hesitate about prescribing chloral would not like to use his own judgment as to whether chloral *plus* glycerin would be any safer?"

To use his own judgment on such a subject intelligently, a physician should know the nature of the compound formed by adding chloral to glycerin, just as he would in deciding in regard to prescribing a product formed by combining potash with bromine. If not informed regarding the chemistry of the latter subject he might think that potash and bromine, both being dangerous poisons, would be only the more poisonous when combined. The physician posted on the subject would, however, recognize the compound as potassium bromide. In a similar manner, a physician not knowing that the product resulting from the reaction between equivalent amounts of chloral and glycerin is a definite chemical compound, differing chemically, physically, physiologically and clinically from chloral. might hesitate about prescribing it because of fear that it was chloral dissolved in glycerin.

Inasmuch as the statement relerred to gives an entirely erroneous idea and implies that the preparation is simply a solution or mechanical mixture of chloral and glycerin, we submit the following:

The reaction which occurs when chloræthanal—trichloraldehyde or chloral—and a higher polyatomic alcohol—the trihydric alcohol $C_3H_5(OH)_3$—or glycerin, are added together, in proper equivalent proportions, produces the chemical compound, trichlorethidene propenyl ether. This reaction was studied and reported by Louis Henry, a celebrated chemist of Louvain, Belgium, as long ago as 1874 (see *Berichte der Deutschen chemischen Gesellschaft*, VII (1874, p. 762). The result of the reaction is a definite chemical compound (trichlorethidene propenyl ether), which, when heated somewhat above 40 degrees C. (104 degrees F.) decomposes into its original components, chloral and glycerin.

The heat developed on admixture of these two substances, the physical properties of the resultant product, and the physiological effects, all prove that the product is a new compound differing in marked degree from chloral. The symbolic formula for this new compound is $C_9H_{11}O_6Cl_3$.

Trichlorethidene propenyl ether is a hypnotic belonging to the methane group. It consists of a viscid mass, or solidified jelly. which will not flow on inverting the container. It can be softened and made to liquefy by heating, or can be changed to a brittle solid on chilling by a freezing mixture, thus differing in its physical condition from either of its original components by being more solid than either. *This proves the formation of a chemical compound* as distinguished from a mere mixture, which would have the tendency to lower the freezing point instead of raising it. as here effected.

What has caused chemists who have made a superficial examination to reach the wrong conclusion that no definite compound is formed has been the fact that when overheated this trichlorethidene propenyl ether is again reverted *into chloral and glycerin.*

Our elixir (Somnos) contains in each 16 Cc. 1.2 Gm. of a concentrated (72 per cent.) trichlorethidene propenyl ether solution in glycerin. When 10 Cc. of this elixir is injected into the veins of a dog, or other animal, the immediate effect is no greater than the effect of injecting the same amount of normal salt solution in the same way; and not until total doses corresponding to twenty times that prescribed are injected does the blood pressure show any permanent fall, or decrease in respiration, and these phenomena are no greater than are characteristic of normal sleep.

Enormous doses are required to produce a lethal effect on animals. corresponding to at least 15 fluidounces of the elixir injected into the veins of a 150-pound man. Sixteen fluidounces of the elixir has been taken by mouth with suicidal intent, and nothing resulted except a long-continued normal sleep, frim which the patient awakened refreshed.

The action of trichlorethidene on the blood is practically negative. This is in great contrast to chloral, which reduces the red blood cells on an average of 32 per cent. It does not reduce hematin, as it was impossible to find hæmatoporphyrinaria in a single case of the many in which it was tested; neither have we had any reports of it doing so.

We are claiming that the product is safer than any known hypnotic; that it produces normal sleep, is less depressing than the bromides and absolutely without any untoward effect upon the heart, respiration and vasomotor centers or the blood. In this we are amply justified by the results of physiological test and clinical experience.

---

* Chloral is a trichlorin derivative of the aldehyde derived from ethyl (æthyl) alcohol and therefore is called trichlorethanal, that is trichlor. indicating that the compound contains three atoms of chlorin, ethan referring to its derivation from ethane or ethyl alcohol and the ending al denoting that it is an aldehyde. Compounds containing one and two chlorin atoms, monochlorethanal and dichlorethanal, are known, but since the compound containing three chlorin atoms is the only one in common use the term chlorethanal is applied to chloral, the prefix tri- being understood. The title, therefore, reads in plain language: "The Chemistry of Chloral."

Therefore, in answer to Professor Stieglitz' question. What physician who would hesitate about prescribing chloral would not like to use his own judgment as to whether chloral *plus* glycerin would be any safer? we unhesitatingly reply: Chloral is conceded to be the most desirable hypnotic known, but owing to its untoward action is unsafe. Trichlorethidene propenyl ether, as prepared by us in the form of elixir (Somnos), possesses all the desirable properties of chloral, but so far as known is free from its untoward effects. Physicians who know this to be the case (and a large and increasing number do know it) prescribe the product in preference to any other hypnotic, and their use of it is founded upon judgment and discretion.

Honest criticism never hurts, but facts half stated, or at least so stated as to lead to erroneous criticism, are unfair, and for that reason we have given the above full information. Very truly yours,

H. K. Mulford Company.

The quotation which calls forth the above letter is from a paper read by Professor Stieglitz in the symposium on "Nostrums," before the Chicago Medical Society—not the Illinois State Medical Society as stated—and published in The Journal of the American Medical Association, May 5, 1906.

The evident intent of Prof. Stieglitz' paper was to show by a concrete example, without mentioning specifically the name of the article, how the glamor of the production of a synthetic had led a prominent and reputable firm to mystify the profession by the use of chemical terms, unintelligible to the mass of the profession, in describing a simple combination of well-known drugs.

Somnos is a proprietary preparation put out by the H. K. Mulford Company, as a:

"Definite chemical product formed by the synthesis of chloræthanal with a polyatomic alcohol radical."

On the label Somnos is stated to be

"A reliable and safe hypnotic and cerebral sedative, free from depressing effects upon the heart, respiration, vasomotor centers."

In the advertisements we are told that:

"Somnos contains no chloral nor paraldehyd and is absolutely free from any depressing action upon the heart or circulation, and has no destructive influences on the red corpuscles of the blood, nor does it cause gastric disturbances by continued use."

It may possibly be unnecessary to suggest that, stripped of all technical verbiage the H. K. Mulford Company acknowledges that Somnos is an unstable compound of chloral and glycerin, and so unstable that it separates and becomes a simple mixture at 104 F. To put it in different words, the firm states that Somnos is a compound of chloral and glycerin and not a mixture, since a chemical union takes place between the two drugs. By referring in the above letter to the work of Henry, the H. K. Mulford Company acknowledges, unintentionally, probably, that this idea of uniting chloral with glycerin is not oriignal with that company. In parentheses it may be said that many attempts have been made in the past to produce compounds of chloral which would not depress the heart; these have all been failures. As Fraenkel states ("Arzneimittel Synthese," second edition, p. 444) compounds of this sort are either so permanent that the chloral effects are lost altogether, or else the chloral is so readily set free that the compound possesses no advantage over the drug. As stated below, experiments show that this is true with the Mulford preparation.

Heretofore the literature did not contain a word to indicate whether Somnos was "chloræthanal alcoholate" or a solution of chloral and glycerin. As a matter of fact it appears to be an elixir containing between 5 and 6 per cent. of the unstable compound of chloral and glycerin. And yet physicians were asked to compare the toxicity of this solution with the undiluted chloral. Even now the attempt to mystify is persisted in. If it really was the intention of the H. K. Mulford Company to tell just what Somnos is, then the amount of chloral represented by a given amount of Somnos would have been stated and not: "Our elixir (Somnos) contains in each 16 Cc. 1.2 Gm. of a concentrated (73 per cent.) trichlorethidene propenyl ether solution in glycerin." We do not hesitate to say that there is not a physician, unless he is also an expert chemist, who could calculate from the data given the amount of chloral represented by a dose of Somnos.

Nearly a year ago, the Council on Pharmacy and Chemistry took up this preparation, Somnos, and chemical examinations revealed that it was a combination of glycerin and chloral, probably a non-stable chemical compound easily separating by heat. Correspondence regarding the matter took place between the Council and the H. K. Mulford Company, without any satisfactory conclusions being reached. The sub-committee having become satisfied regarding the composition of Somnos, namely that it is an unstable compound of chloral and glycerin, proceeded to an investigation by animal experimentation of the claims made by the H. K. Mulford Company regarding its therapeutic effects and safety. While the report has not yet been submitted to the Council, we are informed by those who have conducted the experiments that the results of the experiments show conclusively that the physiologic effects of Somnos are practically identical with those of an elixir of chloral of corresponding chloral strength; respiration, circulation and temperature were equally depressed by the two.

It is to be regretted that when the H. K. Mulford Compa introduced this preparation the firm did not state what now has been forced to state. It is more to be regrette however, that the facts are not now presented in plain language easily understood and not in terms unintelligible except to chemists. Further, why did not the H. K. Mulford Company state exactly how much chloral is represented in a dose of Somnos as marketed, and leave it to those who use it to say whether the same quantity of chloral in Somnos has any different effect than has the same quantity of chloral in a simple elixir?

An Endorsement of the Council on Pharmacy and Chemistry.

At the recent meeting the Pharmaceutical Association of the State of Pennsylvania placed itself on record as endorsing the efforts of the Council on Pharmacy and Chemistry of the American Medical Association. In commenting editorially on this fact, the *Druggists Circular and Chemical Gazette* says:

> Some of the druggists have not been able yet to see the "ultimate gain" to their profession to grow out of the putting down of fraud and deceit in medicine, but light is dawning on more and more of them all the time. The question will be settled when it is settled right—which it will be one of these days. Both in and out of medical circles the insolence of strongly intrenched but unworthy interests is giving way to fear, which in turn will be followed by dismay. Those who read the papers need not be told what is going on among the insurance companies, railroad corporations, the beef packers, and the "bad" trusts generally, and the same kind of revulsion has been stirred up against the evils of the proprietary medicine men. The latter, aided by the "red-clause" portion of the press and such other influences as it can control or buy off, are making a desperate fight, but as the public becomes better and better informed, the fraudulent nostrum army must continue its retreat.

Bile Beans.

In The Journal, Nov. 25, 1905, page 1676, we referred at some length to this nostrum and to the judgment given against it in a British court. A sequel to this appears in the *British Medical Journal*, July 28, from which we quote:

> The second division of the court of session (four judges) at Edinburgh gave judgment on Friday, July 20, in an appeal against a judgment in the outer house, in which the Bile Bean Manufacturing Company, Limited, Greek street, Leeds, sought to interdict an Edinburgh chemist from selling under the name of "Bile Beans" any pills or other articles not made or supplied by the complainers. Interdict was refused in the outer house and the second division adhered to this judgment. The lord-justice-clerk said the bile beans of the complainers were said to be made of Australian vegetable substances discovered by a Charles Forde. The place of the discovery, the mode of it, and the instrument of it were all deliberate inventions, without any foundation in fact. The story was that Charles Forde, who was described as a skilled scientist, had noted the fact that the natives of Australia were free from bodily ailments, and that after research and investigation he had ascertained that that immunity was obtained by the vegetable substances. All that, in every particular, was false. There was never such a person as Charles Forde, and there was no eminent scientist engaged in such research in Australia. The truth was that the complainers had formed a scheme to palm off on the

public a medicine obtained from America, and they created a demand by flooding the country with advertisements, placards, pamphlets, and imaginary pictures. The complainers desired protection for the name "Bile Beans," but being themselves engaged in perpetrating a fraud on the public, they were not entitled to any such protection.

An Instance of the "Patent-Medicine" Habit.

Dr. J. C. Davis, Rochester, N. Y., reports the following interesting case of "patent-medicine" addiction:

"Mrs. Lottie Shaal died, July 10, from an overdose of 'a narcotic of some kind.' The coroner waived an autopsy as the woman was addicted to the 'patent-medicine' habit.

"During the past year she had been taking Cox's Headache Powders, obtained from her grocer. On July 7 she took one box of Cox's Headache Powders; on July 8 a part of a bottle of Hostetter's Bitters, and all of one bottle of Lydia Pinkham's Compound; on the morning of July 9 she went to see a neighboring physician, who gave her a small powder to quiet her nerves. I was unable to ascertain its contents. About noon she went out again and must have got advice or medicine, for she returned home and went to bed. Her two daughters noticed her peculiar actions, and in trying to undress her, discovered a small vial in her stocking. Mrs. Shaal pleaded with them not to disturb her—that she would not take any more. They let her alone for a short time and she got up and must have taken the contents, and have thrown away the bottle, for they have been unable to find it anywhere about the house.

"About 4 o'clock she was taken to St. Mary's Hospital with symptoms of some narcotic and spinal stimulant, and died the next morning, July 10."

Correspondence

Ethyl Chlorid As a General Anesthetic in Minor Operations.

New York, Aug. 22, 1906.

To the Editor:—I noticed an article with the above title in The Journal, August 18, by George F. Hawley, M.D. I desire to call attention to the fact that the inhaler referred to was devised by me for ethyl chlorid narcosis, and has been used by the medical and dental professions for at least three years. He appends the name of "Apperson" to the inhaler, when it is and should be called the antidolorin inhaler, devised by Maurice Green, D.D.S.

No doubt Dr. Hawley has been misinformed or misled, and in proof of my statement I enclose reprints of several articles I have written in the past on this subject, in which are cuts identical to the one used by him.

I do not look for any special credit as the inventor of this device, but I do object to any one taking undeserved credit, or probably imposing on the profession by attaching his name to any apparatus or instrument wrongfully.

Maurice Green, D.D.S.

We submitted the above letter to Dr. Hawley, who writes:

Chicago, Aug. 27, 1906.

To the Editor:—The mask mentioned in my article was represented to me as "Apperson's Mask." Having no reason to question the statement and not being acquainted with the mask of Dr. Green, I used this name in my article. I do not wish to place credit where it is not due, however, and I am, therefore, obliged to Dr. Green for setting me right in the matter.

George F. Hawley.

Interstate Reciprocity and Frauds in Medical Schools.

San Francisco, Aug. 23, 1906.

To the Editor:—In the discussion of the perplexing problem of interstate reciprocity one important phase of the question has apparently been totally overlooked: the necessity of the coöperation of examining boards in the investigation of medical colleges. Forgetful of the fact that the origin of examining boards is directly traceable to the fraudulent acts of medical colleges, boards authorized by law to go behind diplomas are notoriously prone to accept diplomas as *prima facie* evidence of regular and complete college work.

Thus the erudite secretary of the Michigan board writes that in all his career he has never had occasion to reject a diploma from a recognized medical school. Thorough investigation of credentials entails no small amount of labor, but it has already demonstrated that colleges violate the rules contained in their own published announcements and graduate students in violation of the state laws. Repeated rejections of diplomas secured under fradulent conditions has not cured the evil, at least in California, for similar frauds are recurring. The possessors of such diplomas, nevertheless, are beginning to seek new fields. They apply for examination or registration in other states, where their credentials are often accepted without question. Now, were California to reciprocate with these states it would, *volens non volens*, open the door to all such medical bandits, thus defeating the purpose of the law. Surely reciprocity under these conditions can not be founded on justice.

As a specific example of the detection of fraud in applications for license, we cite the following, taken from the official records of the California board:

May 17, 1906, H. R. Painton graduated from the Medical Department of the College of Physicians and Surgeons, San Francisco, and was given a diploma duly signed by Dr. Winslow Anderson, president, and Dr. D. A. Hodghead, dean of said college. July 31, in the office of the State Board of Medical Examiners, H. R. Painton filed his application for a license. In his affidavit mention is made of four consecutive annual courses at the above mentioned school, 1902 to 1906. Inspection of the annual announcements of the College of Physicians and Surgeons showed H. R. Painton's name in four different numbers, thus corroborating the applicant's sworn statement.

Further research, however, developed the following facts: H. R. Painton taught in the grammar school of a neighboring county from 1902 to 1904, i. e., his term of service in the capacity of teacher coincided exactly with the first two years of his alleged attendance at the College of Physicians and Surgeons, San Francisco. Confronted with the above evidence, H. R. Painton admitted having filed a false document, and gave his college attendance as only two courses. The value of H. R. Painton's faculty-bedecked diploma is *nil* in California, but past experience authorizes me to assert its par value in any other state. There, the fradulent product of the no less culpable College of Physicians and Surgeons, San Francisco, will undoubtedly become a stanch advocate of interstate reciprocity.

It may be asked why California recognizes schools proved guilty of fradulent acts. The answer is found in its medical law which authorizes the board to pass on applications and not on colleges.

Two remedies suggested themselves in dealing with frauds in medical colleges: 1. The investigation of colleges by national societies, such as the Association of American Medical Colleges, whose standard has already been recognized by the legislature of seven states and territories, or the medical council of the American Medical Association, whose functions are merely advisory. 2. The coöperation of examining boards in investigating the preliminary educational credentials and the college work of all applicants for license.

In conformity with the latter suggestion the credential committee of the California board has requested that it be notified of all applications for license filed with other state boards by graduates of California colleges.

Dudley Tait.

Insurance Examination Fees.

New York, Aug. 16, 1906.

To the Editor:—In The Journal, August 11, appears an editorial in regard to life insurance fees which is evidently intended to be a fair and conservative statement of the case from your point of view. While conceding the fairness of spirit manifested in the general tenor of your remarks, I can not refrain from calling your attention to the misleading inferences which may be drawn from your statement regarding the effect of the general insurance bill recently enacted by the New York State Legislature.

Any physician not familiar with the facts would be more than likely to infer from your remarks that this law does not in any way affect business written outside of New York State. I presume it was far from your intention to convey such an implication, as you are doubtless aware of the following facts:

1. The companies organized and operating under the laws of New York State must comply with the law limiting the expense of procuring new business. These limitations apply to the entire business of the company, whether written in New York, Oregon, or Central Asia.

2. The companies organized and operating under the laws of other states will not be permitted to enter and to do business in New York State except under limitations identical with those imposed on the New York companies.

The American Medical Association, in appointing a committee to investigate the life insurance situation in advance of passing final judgment on the matter, acted with characteristic dignity and restraint. As your admirable journal is the organ and mouthpiece of the Association, and has assumed the responsibility of molding the opinions of the medical profession on these questions, I am sure you will desire to correct a misleading editorial allusion to a matter of such pivotal importance as the New York insurance law.

Eugene L. Fisk, M.D.
Medical Director.

[Our correspondent evidently labors under the apprehension that our readers do not know that the New York law affects all companies that operate in New York, whether New York companies or not, and we hardly thought it necessary to emphasize this point. There are insurance companies—and many of them—which are still paying the old flat rate of $5.00, and which are doing business in New York.—Ed.]

District Branches of the American Medical Association.

Nashville, Tenn., Aug. 14, 1906.

To the Editor:—Since I learned of the intention on the part of the profession of Kansas, Missouri, Oklahoma, Arkansas and Texas to organize the Southwestern District Branch of the American Medical Association, I have been waiting to see if some one else would not give expression to the opinion that such organizations should be effected immediately all over the United States. Two weeks ago I introduced the discussion of this matter at the meeting of the Nashville Academy of Medicine, and found that every member present viewed the matter as I do. They emphasized their desire for such an organization in our territory by the creation of a committee, consisting of Dr. A. B. Cooke of this city and the undersigned, to undertake the work at once. We have called a meeting for this purpose to be held in Chattanooga October 2, at 9 a. m., in the Read House. This meeting is called for the same time as the meeting of the Tri-State Medical Association. It is my opinion that the Tri-State Association will be glad to transform itself at once into the larger body, which would be named either the Southern District Branch of the A. M. A., or the Southeastern District Branch, probably the former. The states expected to send representatives to this meeting are Kentucky, Tennessee, Georgia, Alabama, Florida, Mississippi and Louisiana. It is not improbable that Kentucky will wish to join the states immediately north of her, in preference to becoming a member of the Southern District Branch. The truth underlying the necessity for these district branches is very clearly expressed in the communication of Dr. F. H. Clark in the August 4 issue of The Journal as follows: "Because of the natural limitations of the state association on the one hand, and the magnitude of the American Medical Association on the other." It must be a fact recognized by every one that the sections of the A. M. A. have grown to be so large that the opportunity for presenting papers, and even of discussing papers, has become very small, especially as concerns the younger members of the profession. If for no other reason, the district branches should be brought into existence, but of course the meetings of these district branches should be held, as provided for already in the constitution, in the fall of the year, or in the early winter, so as never to interfere in the least with the annual sessions of the A. M. A.

In this communication I do not propose to do the thinking for the profession in the various states of the union, but I do propose to make some suggestions that will put them to thinking.

1. The following states are already combined in the formation of the Southwestern District Branch, namely, Kansas, Missouri, Arkansas, Oklahoma and Texas.

2. The following states will constitute, in the near future, the Southern District Branch of the A. M. A., namely, Tennessee, Georgia, Alabama, Florida, Mississippi, Louisiana, and probably Kentucky.

3. Would it not be well for the following states to organize the Southeastern District Branch, namely, South Carolina, North Carolina, Virginia, District of Columbia, Maryland, Delaware and Pennsylvania?

4. How would this do for the Eastern District Branch: New Jersey, New York, Rhode Island, Connecticut, Vermont, New Hampshire, Maine and Massachusetts?

5. How would this do for the Northern District Branch: West Virginia, Ohio, Indiana, Illinois, Michigan—and Kentucky, should she prefer this union to the other mentioned above?

6. How would this do for the Northwest Central District Branch: Wisconsin, Minnesota, Iowa, Nebraska, North Dakota and South Dakota?

7. This for the Northwestern District Branch: Montana, Wyoming, Idaho, Washington and Oregon?

8. This for the Western District Branch: Colorado, New Mexico, Arizona, Utah, Nevada and California?

These several districts would be sufficiently large for furnishing a body of medical men that could be divided into sections for scientific work, but the sections of course should not be so numerous as those of the A. M. A. I would suggest that the following sections would be sufficiently numerous: First, Section on Practice of Medicine, Obstetrics and Diseases of Children, allowing that the practice of medicine should include nervous, mental and cutaneous diseases; second, Section on Surgery and Gynecology; third, Section on Ophthalmology, Otology and Laryngology; fourth, Section on Anatomy, Physiology and Pathology. Therapeutics would naturally fall in the first section.

I trust that if this communication does nothing more, it will at least put the profession to thinking in the direction pointed out. It is presented only in the spirit of suggestion, and not of dictation.

G. C. Savage.

The Attacks on the American Medical Association.

Detroit, Aug. 1, 1906.

To the Editor:—In traveling I meet many members of our Association and hear a good deal of criticism of the management, which pains me very much, and obliges me to defend the organization, and where there is so much talk there must be some cause for it. I also read in the journals a good deal of criticism, and can readily see how it is caused. Undoubtedly a great deal comes from the manufacturers who are financially injured by being exposed; the other comes from the independent journals who resent the statement that there is no use for their existence. In the case of the manufacturers, few will defend them, and I think everybody believes that the good work should go on and be amplified if necessary. As far as the independent journals are concerned, I certainly think there is a place for them. First, there is a place for the various special journals, then there is a place for local medical journals; in fact, I believe every journal, no matter how small, has some good in it and reaches some physician and helps him, and thus does good. Their value may be limited, but still every one does some good. Some think there are too many medical societies; still I believe not. Each one reaches some members that others do not, and thus raises these members up.

The whole thing, it seems to me, is a lack of tact on the part of those in charge of the organization. Take for instance, the Report of the Board of Trustees, as it is published in The Journal of June 16, which is all right, being read simply in abstract, but there is no reason why it should not be printed more in detail. A few pages more of printing matter costs very little more. For instance, the salary list. Why should it not be given in detail; why not state that the Secretary gets $10,000 a year? He certainly earns it. I think he earns twice as much. The members might just as well know it. Why should they not? The expenses of the organizer should be given in detail. He certainly earns it; in fact, the services he renders to the Association is worth five times as much.

I can readily see how the resolution to appoint a committee to investigate the financial condition was opposed by the Trustees, who thought it was a reflection on the management. They have the books investigated by an expert once or twice a year, and always select a different man. They know the books are all right, but the trouble is that the members do not know that. If they would, such a resolution would probably not be offered. If I were a Trustee I would not give any member a chance to offer such a resolution. I would offer it myself and I would insist that the greatest kickers should be put on that committee. That would cure them and then they would see that everything was all right, of which no member really has a doubt. Still, when such a resolution is objected to, it makes a man suspicious, and they ask why should anybody object to that? The Good Book says you must not only avoid evil, but the very appearance of evil. This a good doctrine.

It is just so with the new medical directory. Why could it not be stated exactly what was paid for the list bought by the Association and all the details? Speaking of the medical directory, that will cost probably $75,000 to get it up. With money received from a limited number of advertisements, the price ought to be reduced to about $2.00, and then every member of the Association will get one. At the most it should not cost more than $3.00.

It is such a simple thing. If all these things were known by the members there would be less criticism. The other point is the finances. The Association is growing, has a big income. We do not need to accumulate money. Why, for instance, should not every person who writes an article receive, say, 100 reprints free of charge as a good many medical journals do? If a man wants more he can pay for them and they ought to be given to him at the lowest possible figure or cost price. Why should the bound volume of the Sections cost $1.00 to the members, when the original cost is only about one-third? Why should we accumulate money in bonds and stocks? It is good to have a property of our own, the finest press, and facilities to turn out a good journal, but let us stop there. We may say we want a new building and a larger one. If we do need one, we can put up one, but do it in such a way, that from rents there will be enough to pay the interest on the building and to accumulate a sinking fund that will pay for it in twenty-five or fifty years. Why should the present members pay all that and leave the future generation a valuable property without any efforts of their own? We should be willing to do our share, but we do not need to do everything.

In fact, as the membership grows and the subscription list increases we ought to try and reduce the number of advertisements. We ought to have a journal with virtually no advertisements, and those we have should be charged a good price (just as they have been in the past); decrease the number and increase the price.

If I should be mistaken about one or the other little point, I hope the Trustees will correct me, but all around I simply want to say: Be more open and specific in your statements. Do not resent every little inquiry made, but just jolly them along. Let the independent medical journals alone. Do not charge members more than the actual cost for whatever they get. Devote more money to the chemical and research laboratory, and to establishing of a complete medical library, and give a most perfect review of every medical journal published in the world. That seems to me, should be our constant endeavor. Do not let us quarrel about such little things, but stick together for the good of the race.

J. H. Carstens.

The above letter was forwarded to Dr. T. J. Happel who sends the following reply:

Trenton, Tenn., Aug. 8, 1906.

To the Editor:—Nothing is more unpleasant to me than a controversy, for life is too short to quarrel over the little things. I have read Dr. Carstens' letter, and I regret that he has felt called on to notice the criticisms made by others in regard to the management of the affairs of the Association; yet to notice them in such a way that did one not know that he was a friend of the Association and ready at all times to uphold it, he would be considered as one of the elect who was sitting in judgment on these questions. These criticisms seem to be confined to certain localities where there are perhaps medical men who feel that they are better qualified to edit The Journal and to manage the affairs of the Association than is now being done. In various ways I come in contact with many physicians, and I have yet to find the first one, except the few disgruntled ones who were at the Boston session, who complain of the management. The criticisms on the part of the various physicians spoken of in almost every case could be referred to "a sore toe," or some other like cause of irritation.

The independent medical journals owned by physicians are usually run for profit alone, and of course the war made on unethical advertising hurts their "toe." They claim not to want to publish unethical advertisements, and yet they continue to do so for the money which they receive, and their opposition is due to the fact that The Journal has shown up the fraudulent nature of these advertisements. If they cut out these advertisements they lose money, hence they complain, but they make their journal better. There is a place for all ethically conducted private journals, and instead of The Journal, A. M. A., injuring them, it is an indirect benefit to them, for as The Journal's rate of advertising is proportioned to its circulation, the private journal will get much that The Journal can not get. Some of these journals are doing noble work, and the House of Delegates was outspoken on this subject at Boston.

While the journals already mentioned are to be commended, there are many journals sent out by and in the interest of the manufacturing chemists to laud their own products. Such as these can not be handled decently in an article limited in space, and hence, they must be ignored.

The state journals are rapidly becoming essentials in well organized medical associations. They furnish state and county medical news—reporting the proceedings of the state and county medical societies. Of course this might lessen the amount of free material for the private journals, but the private journal has no right to complain of this.

Manufacturers of some of the proprietary medicines complain because the worthlessness of many of their products has been shown up through the work of the Council on Pharmacy and Chemistry of the A. M. A. I agree with the Rev. Sam Jones in cases of such complaints, when he says that "if you throw a brick into a crowd you can tell who has been hit, because he always makes an outcry." Those who are complaining most loudly are the ones who have put on the market the worst drugs, and who may have come in contact with the "Pure Food Bill" passed by the last Congress.

However, I would have nothing to say in answer to Dr. Carstens' letter had it not been for the insinuations against the Board of Trustees. He says that there is a lack of tact on their part in the management of the affairs of the Association, and illustrates this by a reference to the report of the Board of Trustees, which he says was read "simply in abstract" (of course he means in the House of Delegates). Dr. Carstens knows, or should know, and if he was not in the House at the time the report was called for, then his friend, Dr. H. O. Walker, should have informed him, that before the report of the Board of Trustees was read, at the request of the chairman of the board, when the report was called for, instead of being read at the morning session, a copy of the report was given every

Any physician not familiar with the facts would be more than likely to infer from your remarks that this law does not in any way affect business written outside of New York State. I presume it was far from your intention to convey such an implication, as you are doubtless aware of the following facts:

1. The companies organized and operating under the laws of New York State must comply with the law limiting the expense of procuring new business. These limitations apply to the entire business of the company, whether written in New York, Oregon, or Central Asia.

2. The companies organized and operating under the laws of other states will not be permitted to enter and to do business in New York State except under limitations identical with those imposed on the New York companies.

The American Medical Association, in appointing a committee to investigate the life insurance situation in advance of passing final judgment on the matter, acted with characteristic dignity and restraint. As your admirable journal is the organ and mouthpiece of the Association, and has assumed the responsibility of molding the opinions of the medical profession on these questions, I am sure you will desire to correct a misleading editorial allusion to a matter of such pivotal importance as the New York insurance law.

Eugene L. Fisk, M.D.
Medical Director.

[Our correspondent evidently labors under the apprehension that our readers do not know that the New York law affects all companies that operate in New York, whether New York companies or not, and we hardly thought it necessary to emphasize this point. There are insurance companies—and many of them—which are still paying the old flat rate of $5.00, and which are doing business in New York.—Ed.]

District Branches of the American Medical Association.

Nashville, Tenn., Aug. 14, 1906.

To the Editor:—Since I learned of the intention on the part of the profession of Kansas, Missouri, Oklahoma, Arkansas and Texas to organize the Southwestern District Branch of the American Medical Association, I have been waiting to see if some one else would not give expression to the opinion that such organizations should be effected immediately all over the United States. Two weeks ago I introduced the discussion of this matter at the meeting of the Nashville Academy of Medicine, and found that every member present viewed the matter as I do. They emphasized their desire for such an organization in our territory by the creation of a committee, consisting of Dr. A. B. Cooke of this city and the undersigned, to undertake the work at once. We have called a meeting for this purpose to be held in Chattanooga October 2, at 9 a. m., in the Read House. This meeting is called for the same time as the meeting of the Tri-State Medical Association. It is my opinion that the Tri-State Association will be glad to transform itself at once into the larger body, which would be named either the Southern District Branch of the A. M. A., or the Southeastern District Branch, probably the former. The states expected to send representatives to this meeting are Kentucky, Tennessee, Georgia, Alabama, Florida, Mississippi and Louisiana. It is not improbable that Kentucky will wish to join the states immediately north of her, in preference to becoming a member of the Southern District Branch. The truth underlying the necessity for these district branches is very clearly expressed in the communication of Dr. F. H. Clark in the August 4 issue of The Journal as follows: "Because of the natural limitations of the state association on the one hand, and the magnitude of the American Medical Association on the other." It must be a fact recognized by every one that the sections of the A. M. A. have grown to be so large that the opportunity for presenting papers, and even of discussing papers, has become very small, especially as concerns the younger members of the profession. If for no other reason, the district branches should be brought into existence, but of course the meetings of these district branches should be held, as provided for already in the constitution, in the fall of the year, or in the early winter, so as never to interfere in the least with the annual sessions of the A. M. A.

In this communication I do not propose to do the thinki for the profession in the various states of the union, but I propose to make some suggestions that will put them thinking.

1. The following states are already combined in the fo tion of the Southwestern District Branch, namely, Kans Missouri, Arkansas, Oklahoma and Texas.

2. The following states will constitute, in the near futu the Southern District Branch of the A. M. A., namely, T nessee, Georgia, Alabama, Florida, Mississippi, Louisiana, probably Kentucky.

3. Would it not be well for the following states to org the Southeastern District Branch, namely, South Carol North Carolina, Virginia, District of Columbia, Maryland, D aware and Pennsylvania?

4. How would this do for the Eastern District Branch: N Jersey, New York, Rhode Island, Connecticut, Vermont, N Hampshire, Maine and Massachusetts?

5. How would this do for the Northern District Branc West Virginia, Ohio, Indiana, Illinois, Michigan—and Ke tucky, should she prefer this union to the other mention above?

6. How would this do for the Northwest Central Dist. Branch: Wisconsin, Minnesota, Iowa, Nebraska, North kota and South Dakota?

7. This for the Northwestern District Branch: Monta Wyoming, Idaho, Washington and Oregon?

8. This for the Western District Branch: Colorado, N Mexico, Arizona, Utah, Nevada and California?

These several districts would be sufficiently large for fi nishing a body of medical men that could be divided into tions for scientific work, but the sections of course should be so numerous as those of the A. M. A. I would g that the following sections would be sufficiently numer First, Section on Practice of Medicine, Obstetrics and Disea of Children, allowing that the practice of medicine should clude nervous, mental and cutaneous diseases; second, Secti on Surgery and Gynecology; third, Section on Ophthalmol Otology and Laryngology; fourth, Section on Anatomy, P ology and Pathology. Therapeutics would naturally fall the first section.

I trust that if this communication does nothing more, it at least put the profession to thinking in the direction point out. It is presented only in the spirit of suggestion, and not dictation.

G. C. Savage

The Attacks on the American Medical Association.

Detroit, Aug. 1, 19

To the Editor:—In traveling I meet many members of Association and hear a good deal of criticism of the mana ment, which pains me very much, and obliges me to def the organization, and where there is so much talk there m be some cause for it. I also read in the journals a good de of criticism, and can readily see how it is caused. Undoubte a great deal comes from the manufacturers who are financia injured by being exposed; the other comes from the independe journals who resent the statement that there is no use their existence. In the case of the manufacturers, few defend them, and I think everybody believes that the work should go on and be amplified if necessary. As far the independent journals are concerned, I certainly think is a place for them. First, there is a place for the vario special journals, then there is a place for local medical journal in fact, I believe every journal, no matter how small, has good in it and reaches some physician and helps him, and does good. Their value may be limited, but still every does some good. Some think there are too many medical s cieties; still I believe not. Each one reaches some that others do not, and thus raises these members up.

The whole thing, it seems to me, is a lack of tact on t part of those in charge of the organization. Take for insta the Report of the Board of Trustees, as it is publish in The Journal of June 16, which is all right, being

Therapeutics would naturally fall in the first section.

I trust that if this communication does nothing more, it will at least put the profession to thinking in the direction pointed out. It is presented *only in the spirit of suggestion, and not of dictation.* G. C. Savage.

The Attacks on the American Medical Association.

Detroit, Aug. 1, 1906.

To the Editor:—In traveling I meet many members of our Association and hear a good deal of criticism of the management, which pains me very much, and obliges me to defend the organization, and where there is so much talk there must be some cause for it. I also read in the journals a good deal of criticism, and can readily see how it is caused. Undoubtedly a great deal comes from the manufacturers who are financially injured by being exposed; the other comes from the independent journals who resent the statement that there is no use for their existence. In the case of the manufacturers, few will defend them, and I think everybody believes that the good work should go on and be amplified if necessary. As far as the independent journals are concerned, I certainly think there is a place for them. First, there is a place for the various special journals, then there is a place for local medical journals; in fact, I believe every journal, no matter how small, has some good in it and reaches some physician and helps him, and thus does good. Their value may be limited, but still every one does some good. Some think there are too many medical societies; still I believe not. Each one reaches some members that others do not, and thus raises these members up.

The whole thing, it seems to me, is a lack of tact on the part of those in charge of the organization. Take for instance, the Report of the Board of Trustees, as it is published in The Journal of June 16, which is all right, *being read*

delegate, and to every one who was in the house at that time, with the request that before the House of Delegates reconvened for the afternoon session it should be carefully examined, to the end that when read, any and all members in the house might call for any information desired, not fully set forth in the report. At the afternoon session of the house, after several other matters had been disposed of, "The Report of the Board of Trustees for the year ending Dec. 31, 1905," was called for. Under the direction of the board this report was presented by the chairman. He read carefully and deliberately every part of the report that was deemed of sufficient importance to demand any special comment. As the financial part of the report was printed in detail, except an itemized statement of salaries, and the expense account of the organizer, Dr. McCormack; the receipts and expenditures were not read singly, but the sum total of each was stated, and then a few of the larger items read—the page of the report being called in every case as the reading progressed. These debit and credit tables were prepared by an auditing company of Chicago, chartered under the laws of Illinois, having no interest in the result of its examination; its sole object being to investigate the books and vouchers and accounts of The Journal office, and of the Treasurer. In order to refresh the memories of Dr. Carstens and of others who take the same view that he does of the work of The Journal office and of that of the Board of Trustees, I copy from The Journal, June 16, the last clause of the report of the Investor Audit Company, which examined the books for the Board last January:

> We have examined, properly approved and receipted vouchers for all expenditures, with the exception of a few which had not been returned by the bank at the time of our visit. We shall audit same on our next visit to the office of the Association. We counted the cash on hand and verified the cash in bank with statements furnished us by the bankers. The securities in possession of the Trust Company were examined and found to be intact. In addition to the above, we have verified the footings of the cash book and made such other checks as in our opinion were deemed necessary for the protection of the Association.
>
> Considering the amount of detail handled by the Accounting Department, we found the work to be in excellent condition. There appears to be a continued improvement in the manner of handling the accounts and office work.
>
> We will be pleased to furnish you with any other information that you may desire. Yours faithfully,
>
> E. M. Mill, Manager.

Dr. Carstens complains that the salary list was not printed in full in the report. Such a list never appears in the report of any well-managed business association. The Board of Trustees, recognizing the right of every member of the House of Delegates and of any member of the Association to such information, carried to the session a sheet having every item on it, from which to read anything asked for. We did not feel that it was necessary to publish to the world the amount paid the editor and the 150 to 175 other employés, including the girls engaged by the hour in the mailing department. As was forcibly stated on the floor of the house by Dr. Montgomery, the salary of the editor was fixed, when he was elected, at $5,000 per annum, to be gradually increased in proportion to the results produced till it reached the sum of $10,000, which amount he has received since March of last year. Whether or not he has merited that amount, judge ye. The Board of Trustees thinks that he has. How well Dr. Simmons has done his work can be easily shown by reference to The Journal, July 9, 1898. The report of the Board of Trustees, made at Denver in that year, showed the total receipts of The Journal office, including $20,000 drawn from the Treasurer, to have been $47,140.07; expenses, $45,644.17, leaving a balance of less than $1,500 in The Journal office. The Treasurer's report showed a balance in his hands of $14,692.72. Ten thousand dollars of this amount was put aside for emergencies, making a sinking fund of $13,000. The weekly average issue of The Journal was then 11,470 copies, as compared with 38,000 for the year ending Dec. 31, 1905. I am glad that Dr. Carstens does not object to the salary paid our editor.

Had the full pay-roll of The Journal office been printed in the report, The Journal would have been at the mercy of any human vulture that might have desired to injure it, by attempting to entice from it any employé, by offering a few more dollars than he or she was receiving. No business man, firm, or corporation is ever guilty of such a stupendous piece of folly. Further:—the payroll is constantly changing, but all of the labor used in the mechanical and composing departments must be paid for at union rates.

In addition to the sheet containing the salary account, there was also on hand in Boston the sheet which contained the organization expense account, which was given to Dr. Coe, with permission to publish it if he wished to do so. The salary account was also put into his hands so that each and every one, whether a "kicker" or not, might read and compare, but not publish without permission of the House of Delegates. Dr. Carstens or Dr. Walker could have published the organization statement, had either of them wished to do so, for it was put in the hands of Dr. Coe to do with it as he pleased, but both report sheets were returned to the Chairman of the Board before the afternoon session adjourned. This makes it perfectly plain that the board had nothing to conceal and was wishing to conceal nothing.

The employment of Dr. McCormack as organizer since the annual session, in 1904, has been done under the order of the House of Delegates. He has been paid $5,000 a year and his expenses ever since he entered on the duties of that position. The Trustees felt one year ago that the organization had reached such a stage that this expense might be dispensed with, but on the direct request of the House of Delegates continued his services for another year, as they did again at the last session.

I am of the opinion that the House of Delegates would not have wanted to listen to the reading of a report of Dr. McCormack's traveling expenses, made up of railroad fares, board and incidentals from one place to another of his itinerary. These and similar accounts are all submitted to and passed on by the Board of Trustees, after which they go to the Audit Company. Every item of this and of all other accounts is on file in The Journal office and is open to the inspection of every member of the Association who may call at the office of The Journal. I may add parenthetically that I have had a personal experience in investigating a few business matters for friends in the office, and it was no trouble to find anything that was wanted. It always seemed to be a pleasure for the book-keeping department to look up any matter called for. The board will gladly furnish a report, covering all the itemized details of the business if the House of Delegates wishes it, and it will welcome any investigation made under the order of the House of Delegates. It is an utter absurdity to suggest an investigation of a business of the magnitude of The Journal office by a committee of physicians who are not practical book-keepers. The Board of Trustees long since abandoned any such piece of folly, and has the work done by expert accountants. Two audit companies have been employed since my connection with the board. If another investigation is wanted apart from that made by the board, then let there be selected by a committee in no wise connected with the management of The Journal a different expert accountant, and let him be sent there by the president of the Association with directions to go through the office in a systematic way and to send in his separate report to the next session of the Association. A committee of physicians would be a useless addendum to a financial investigation. Let it be understood that The Journal office and its affairs are open to the members of the Association at any time.

The organization expense account as handed Dr. Coe is as follows:

ORGANIZATION EXPENSE, 1905.

Dr. J. N. McCormack, salary	$4,999.92
Dr. J. N. McCormack, expense bill, June 13, 1904, to July, 1905	1,453.90
Drs. Ohls and Green	875.00
Express charges and postage	42.92
Expense to agents account of local society work	259.00
Jobbing	166.30
	$7,797.04

1906.

Dr. J. N. McCormack, salary, January to April, inclusive	$1,666.64
Dr. J. N. McCormack, expense bill, Sept. 4, 1905, to December, 1905	863.00
Jobbing, express, etc.	118.60
	$2,648.24

Drs. Ohls and Green are in The Journal office, but such of their time as is devoted to the work of Dr. McCormack is

The last section of Dr. Carstens' article, wherein he gives the Trustees advice, can be answered in one sentence. "Advice is the cheapest commodity on the market." This reply is written in no contentious spirit but to let the members of the Association know that THE JOURNAL force, from editor down to mailing girls, are doing their whole duty, and that the Board of Trustees is attempting conscientiously to do the work assigned them, without fear or favor.

We would add further that we welcome honest criticism, and when it is not made from impure motives (with which we do not charge Dr. Carstens, for we believe him to be a true friend to THE JOURNAL) we are ever ready to answer it to the best of our ability.

T. J. HAPPEL,
Chairman Board of Trustees.

Marriages

EDWARD C. ROSENOW, M.D., Chicago, to Miss Lydia Senty, of Arcadia, August 1.

IRA F. GOSE, M.D., Eureka Utah, to Miss Willie Sallee, of Danville, Ky., August 15.

JAMES M. COOPER, M.D., Detroit, Mich., to Miss Mattie Craft of Grass Lake, Mich., August 22.

IRVIN S. WORKMAN, M.D., Gambier, Ohio, to Miss Ruth Klinger, of Delaware, Ohio, August 14.

C. LOUIS HOEFFLER, M.D., Omaha, Neb., to Miss Marie E. Mallette, of Chelsea, Mass., August 19.

ISADOR S. TROSTLER, M.D., Orleans, Neb., to Miss Ruphelle Luce, of New Vineyard, Me., August 16.

PEDER SATHER BRUGUIERE, M.D., to Miss Nannie King, both of San Francisco, at Reno, Nev., August 20.

GEORGE HOPKINSON, M.D., Boston, Mass., to Miss Helen Wright Andrews, of Binghamton, N. Y., July 14.

WALTER REMSEN BRINCKERHOFF, M.D., formerly of Boston, but now of Honolulu, to Miss Nellie M. White, of Winchendon, Mass., at Honolulu, August 25.

Deaths

Reynaldo Juan Fitzgerald, M.D. Albany (N. Y.) Medical College, 1882; a member of the Association of Military Surgeons of the United States; surgeon of the Thirteenth Minnesota Infantry, U. S. V., and on duty with that command in the Philippine Islands; a member of the state and county medical societies; the first man to volunteer at the organization of the Minnesota National Guard in 1882, and major-surgeon in that regiment during the Spanish-American War; medical director of the Minnesota National Guard, with the rank of colonel on his return to the United States, and at the time of his death major and surgeon National Guard of Minnesota and assigned to the First Infantry; a prominent practitioner of Minneapolis, died at his home in that city, August 18, as the result of disease contracted in the Philippine Islands, aged 45.

Godfrey R. Martine, M.D. University of Vermont Medical Department, Burlington, 1862, a member of the American Medical Association; International Medical Congress, 1900; New York State Medical Association; formerly president of the Warren County Medical Society, the Tri-County Medical Society, and Warren County Medical Association, who established the Glens Falls Hospital in 1885 and was consulting surgeon for that institution; formerly coroner and health officer of Warren County; one of the oldest and most prominent physicians of Glens Falls, was struck, August 8, by a Hudson Valley Railway express car, two miles north of Glens Falls, and instantly killed, aged 69.

Charles David Hurt, M.D. University of Georgia Medical Department, Augusta, 1881; a member of the American Medical Association; ex-president of the Atlanta Society of Medicine; formerly professor of materia medica in the Southern Medical College, Atlanta; chief surgeon Georgia Railway and Electric Company; professor of therapeutics in the Atlanta School of Medicine; president of the medical board of Wesley Memorial Hospital and a member of the medical board of Grady Hospital; for thirteen years a resident of Atlanta; a Confederate veteran, died at his home in Inman Park, Atlanta, after an illness of more than eight months, August 12, aged 63.

James E. Smith, M.D. Albany (N. Y.) Medical College, 1889, and valedictorian of his class; a member of the Albany County (N. Y.) Medical Society and coroner of the county from 1890 to 1893; a lieutenant during the Spanish-American War and on duty in the Hawaiian Islands; afterward assistant surgeon of the Tenth Battalion, N. G. N. Y.; senior vice-commander of the Department of New York of the Spanish-American War Veterans, was stricken with paralysis at his home in Albany, August 13, and fell, fracturing his skull, dying at the Albany Hospital twenty-four hours later, aged 38.

Hunter P. Cooper, M.D. Medical Department of Columbian University, Washington, D.C., 1883; professor of obstetrics and gynecology in the Atlanta College of Physicians and Surgeons; gynecologist to Wesley Memorial Hospital, Atlanta; local surgeon of the Georgia Railway, Nashville, Chattanooga & St. Louis Railroad, Atlanta & Western Railway and Western of Alabama Railway; a member and ex-president of the Atlanta Society of Medicine, and a member of the Medical Association of Georgia, died at his home in Atlanta, August 24, from septicemia, aged 46.

William Octah Vance, M.D. Louisville National Medical College, 1889; Illinois Medical College, Chicago, 1895; one of the founders of the Louisville National Medical College and a professor in and member of the board of trustees of the institution; for twenty-five years principal of the colored high school in New Albany, Ind., and one of the most influential colored men of his city, died from heart disease at his home, August 16, aged 50.

Joseph W. V. R. Plummer, M.D. Southern Medical College, Atlanta, Ga., 1884; formerly surgeon in the Navy; at the time of his death city health officer of Key West, Fla., and twice mayor of that city, who had done special work in the treatment of yellow fever and other tropical diseases; some time commander of the Department of Florida in the Grand Army of the Republic, died at his home in Key West, August 8, from diabetes, after an illness of four months, aged 64.

Frank P. Grove, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1901, a member of the Medical Society of the State of Pennsylvania and of the Huntingdon County Medical Society, died at his home in Alexandria, Pa., August 20, from tuberculosis, after an illness of eighteen months, aged 30. The county medical society adopted appropriate resolutions regarding the death of Dr. Grove.

Robert J. Preston, M.D. University of Virginia Department of Medicine, Charlottesville, 1867; a member of the American Medical Association, superintendent of the State Hospital for the Insane, Marion, Va., and one of the most prominent alienists of that state, died suddenly from heart disease in New York City, August 20, while on his way to attend the meeting of the British Medical Association at Toronto, aged about 60.

Cornelius C. Beard, M.D. New Orleans (La.) School of Medicine, 1849; a veteran of the Civil War; one of the founders of the New Orleans School of Medicine and professor of anatomy in that institution; for many years a practitioner of New Orleans, died at his home in Brookline, Mass., May 15, after a prolonged illness, aged 78.

William R. Van Tuyl, M.D. Kansas City (Mo.) Medical College, 1889, contract surgeon in the United States Army during the Spanish-American War and on duty in the Philippine Islands, a prominent physician of Leavenworth, Kan., died at his home from heart disease, August 19, after a lingering illness, aged 42.

Bernardino Calabrese, M.D. University of Naples, Italy, 1861; for several years a surgeon in the Italian army and for a long time mayor of his native town of Samfele; for fifteen years a practitioner of Buffalo and official physician to the Italian consulate, died at his home, August 16, after a brief illness, aged 68.

Hugh Henry McIntyre, M.D. University of Georgetown Medical Department, Washington, D. C., of Randolph, Vt.; a veteran of the Civil War; special agent of the United States in connection with the arbitration at Paris in 1892 and 1893, died suddenly from heart disease at Barnard, Vt., August 13, aged 60.

Frederick J. Owens, M.D. Philadelphia College of Medicine and Surgery, 1853; surgeon of the First Delaware Volunteer Infantry during the Civil War; formerly a practitioner of Harrington, Del., died at his home in Denton, Md., from senile debility, August 16, aged 84.

Armstead Jackson Patterson, M.D. Jefferson Medical College, Philadelphia, 1867, a member of the Medical Association of North Carolina, died at his home in Liberty, N. C., July 5, from septicemia following a double pyonephrosis, after an illness of four months, aged 65.

O'Connor, R. P., asst.-surgeon, granted thirty days leave of absence.

Noble, R. E., asst.-surgeon, leave of absence extended one month.

Wing, Franklin F., dental surgeon, ordered to report to commanding general, Camp of Instruction near Fort D. A. Russell, Wyo., for duty.

Cass, W. E., contract surgeon, reports at Fort Worden, Wash., for temporary duty.

Wertenbaker, C. I., dental surgeon, returned to Madison Barracks, N. Y., from leave of absence.

Cutliffe, William O., contract surgeon, arrived at San Francisco, Cal., on three months' leave of absence.

Sanford, Joseph L., contract surgeon, arrived at San Francisco, Cal., on one month's leave of absence.

Cattermole, Charles A., contract surgeon, ordered to proceed from Manhattan, Nev., to San Francisco, Cal., and take transport to sail from the latter place on or about Sept. 5, 1906, for the Philippine Islands, and on arrival at Manila to report in person to the commanding general, Philippines Division, for assignment to duty.

Prentice, Arthur D., contract surgeon, relieved from duty in the Philippines Division, and ordered to proceed by first available transport to San Francisco, and on arrival report by telegraph to the Military Secretary of the Army for further orders.

Navy Changes.

Changes in the Medical Corps U S. Navy, for the week ending Aug. 25, 1906:

Elliot, M. S., surgeon, detached from the *Florida* and ordered to the *St. Louis*.

Iden, P. A. surgeon, to the *Florida*.

Pease, T. N., asst.-surgeon, resignation as an assistant surgeon in the Navy accepted to take effect August 21, 1906:

Jones, A. McK., acting asst.-surgeon, to the Naval Hospital, Norfolk, Va.

Baker, M. C., acting asst.-surgeon, to the Naval Hospital, Newport, R. I.

Longabaugh, R. I., acting asst.-surgeon, ordered to Naval Hospital, Mare Island, Cal.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Aug. 22, 1906:

Pettus, W. J., assistant surgeon-general, granted leave of absence for thirteen days, from August 20.

Rosenau, M. J., P. A. surgeon, granted leave of absence for fourteen days from August 20.

Nydegger, J. A., P. A. surgeon, leave of absence granted for three months from August 11, amended to read one month and fifteen days from September 3.

Cumming, H. S., P. A. surgeon, granted leave of absence for one month from September 15.

Anderson, J. F., P. A. surgeon, detailed as temporary chairman of board convened July 2, 1906, to investigate the origin and prevalence of typhoid fever in the District of Columbia, to serve during the absence of P. A. Surgeon M. J. Rosenau, on fourteen days' leave from August 20.

Hunt, Reid, chief Division of Pharmacology, and Roehrig, A. M., pharmacist, detailed to represent the service at the 54th Annual Meeting of the American Pharmaceutical Association at Indianapolis, September 3.

Porter, J. Y., sanitary inspector, granted leave of absence for seven days from August 6.

Dunn, James, acting asst.-surgeon, granted leave of absence for twenty-three days from August 13.

Townsend, F., acting asst.-surgeon, granted leave of absence for seven days.

Goodman, F. S., pharmacist, granted leave of absence for ten days, from September 10.

Ryder, L. W., pharmacist, granted leave of absence for twenty-five days from August 20.

Carlton, C. G., pharmacist, granted leave of absence for twenty-four days on account of sickness from July 9.

Hall, L. P., pharmacist, granted leave of absence for seven days from August 17, under Paragraph 210 of the Regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended August 24, 1906:

SMALLPOX—UNITED STATES.

Illinois: Chicago, August 11-18, 2 cases.
Louisiana: New Orleans, August 4-18, 14 cases.
Oregon: General, July 1-31, 11 cases.
Tennessee: Knoxville, August 4-11, 1 case.
Utah: General, July 1-31, 32 cases.
Wisconsin: Appleton, August 11-18, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, July 7-14, 2 cases.
Brazil: Bahia, June 30-July 28, 15 cases; Rio de Janeiro, July 1-8, 1 case; July 22-29, 2 cases, 1 death.
Chile: Antofagasta, July 1-13, 23 cases, 4 deaths.
France: Paris, July 21-August 4, 7 cases.
India: Calcutta, June 30-July 7, 11 deaths; Madras, July 7-13, 3 deaths.
Russia: Odessa, July 21-28, 3 cases, 1 death; St. Petersburg, July 7-28, 8 cases, 3 deaths.
Siberia: Vladivostock, June 28-July 5, 3 cases.
Spain: Seville, July 1-31, 20 deaths.
Turkey: Constantinople, July 21-29, 1 death.
Uruguay: Montevideo, June 1-30, 1 death.

YELLOW FEVER—UNITED STATES.

Louisiana: New Iberia, August 19, 1 case.

YELLOW FEVER—FOREIGN.

Mexico: Merida, July 29-August 4, 6 cases, 2 deaths; Progreso August 7, 1 case, 1 death.

CHOLERA.

India: Calcutta, June 30-July 7, 18 deaths; Madras, July 7-13 12 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, August 30, 1 death.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, July 1-8, 2 cases; July 22-29, 1 case.
Chile: Antofagasta, July 1-13, 4 cases, 2 deaths.
China: Hongkong, June 30-July 7, 12 cases, 7 deaths.
Egypt: Alexandria, July 13-27, 11 cases, 6 deaths; Port Said July 17, 1 case; Suez, July 14-27, 6 cases, 3 deaths.
Assioot Province: Assioot, July 19-28, 2 cases.
India: General, June 30-July 7, 630 cases, 536 deaths; Calcutta June 30-July 7, 9 deaths.
Japan: Formosa, General, July 10-30, 45 cases, 40 deaths.
Persia: Seistan, June 23-July 22, 90 cases, 85 deaths.
Peru: Lima, July 14-21, 1 case; Mollendo, July 4-18, 2 cases 2 deaths.

Society Proceedings

COMING MEETINGS.

Medical Soc. of the Missouri Valley, Council Bluffs, Iowa, Sept. 6-7
Med. Soc. of the State of Pennsylvania, Bedford Springs, Sept. 11-1
Washington State Medical Association, Spokane, Sept. 11-13.
Assn. of Military Surgeons of the U. S., Buffalo, N. Y., Sept. 11-1
Am. Assn. of Obstetricians and Gynecol., Cincinnati, O., Sept. 20-2
American Electro-Therapeutic Association, Philadelphia, Sept. 18-2

AMERICAN ORTHOPEDIC ASSOCIATION.

Twentieth Annual Meeting, held in Toronto, Canada, Aug 20-22, 1906.

The President, Dr. Bart E. MacKenzie, Toronto, in the Chai

Dr. MacKenzie delivered the president's annual addres He referred to the great problems that now confront the medical profession as a whole. These problems should be recognized to relate as closely to orthopedic surgeons as to an physicians; the specialist in any branch of medical work mus always remember that first of all he is a member of the grea profession of medicine, and that what affects the profession a a whole affects him. Subjects that especially unite orthopedi surgery to general medicine are tuberculosis and fresh fractures. Perhaps no group of men are so well qualified to car for fresh fractures as orthopedic surgeons. The orthopedist' experience in local treatment trains him especially well to trea also early paralyses, and neuroses that simulate organi lesions.

The president referred to the deaths of members durin the year and Dr. Roswell Park, Buffalo, spoke of the pathology in the case of Dr. Louis A. Weigel, one of the membe who had died. He said that the x-ray dermatitis on Dr. Weigel hands came on about two years before he died. The right han and part of the left had to be amputated on account of carc nomatous development, and in February, 1906, metastase were removed from the axillæ, and the breast was amputate Dr. Weigel's illness was exceedingly painful, but was mos bravely borne. He died a victim to his devotion to the Roentgen ray.

With reference in general to the effect of the Roentgen ra on the surface structures, Dr. Park said that apparently th blood vessels were primarily affected, producing blood stasi A toxic substance is evolved, and this produces the dermatiti The Roentgen ray can produce keratosis, but leads to cance only indirectly through chronic irritation in the same wa that a burn by ordinary heat may lead to malignant development.

Officers Elected.

The following officers were elected: President, Dr. Joel Goldthwait, Boston; vice-presidents, Dr. Henry Ling Taylo New York; and Dr. Ansel G. Cook, Hartford, Conn.; secretar Dr. Robert B. Osgood, Boston; treasurer, Dr. E. G. Bracket Boston; executive committee, Dr. John Ridlon, Chicago; D D. R. Townsend, New York; Dr. H. Augustus Wilson, Phi adelphia; Dr. Goldthwait and Dr. Osgood, ex-officio.

Sir Thomas Barlow, M.D., London; Sir James Barr, M.D., Liverpool; Sir William Broadbent, M.D., London; Dr. Henry William Langley Brown, West Bromwich, chairman of the council of the British Medical Association; Mr. George Cooper Franklin, F.R.C.S., Leicester, past-president of the British Medical Association; Dr. W. Dobinson, Halliburton, London; Sir Victor Horsley, F.R.C.S., London; Dr. Donald McAlister, Cambridge, president of the British Medical Council, and Sir William Julius Mickle, London.

THE GENERAL ADDRESSES.

Teaching of Obstetrics.

This subject was chosen by Dr. W. S. A. Griffith for the address on obstetrics. He says that some of the obvious imperfections in the teaching of obstetrics are for the most part due to the difficulty of providing practical clinical teaching. When attended by students who have had the necessary preliminary clinical teaching the out-patient maternities provide the most important and valuable training that any medical student can obtain, for as in private practice he is then placed almost entirely on his own resources. Another factor which has delayed the provision of adequate teaching in obstetrics, is the old ingrained idea that the process of labor is a single function of Nature, requiring for the most part a competent nurse only and that the practitioners of obstetrics, although recognized in theory as of equal standing, are to be looked down on in comparison with their colleagues in the other great branches of medicine and surgery. As the result of this, both in teaching and in examinations, the study of obstetrics has been relegated to a position totally unworthy of its immense importance to the practitioner and to the national welfare. Another defect in the teaching is due to the fact that the lecturers frequently have had little experience in the practice of obstetrics. The lecturer presides over no obstetric clinic, and has often had but little experience. He is an obstetrician in name, not in practice. In many of the provincial schools the lecturer is a successful general practitioner, to whom the fates have given a large obstetric experience, but whose experience as a teacher may have been quite inadequate. To place the teaching of obstetrics on the same basis as the teaching of medicine and surgery, it is essential that the clinical teaching be given in hospitals provided for the purpose, where a sufficient and continuous series of patients can be admitted, and having a large externe department where the advanced students can attend patients at their own homes. Lying-in wards in a general hospital would be equally valuable if there were a sufficiently large number of beds to ensure a regular series of patients in sufficient numbers. A large number of cases is less of a necessity than a continuous series. Every clinical teacher of obstetrics should be a practitioner of obstetrics having charge of the obstetric wards and externe maternity department, whose office as professor or lecturer would necessarily terminate with the cessation of his clinical duties. While it is perfectly clear that there are many general practitioners able to give excellent instruction in some of the details of practical midwifery, it is equally certain that there are many others whose methods of practice, especially in the disregard of aseptic precautions, would make them dangerous teachers, and would lead to the continuance of methods which tend to the perpetuation of the still high mortality from puerperal fever. The training of the student is also discussed.

Technic of Operations on Central Nervous System.

Sir Victor Horsley discussed this subject in his address in surgery. He said that the advance in technic of the surgical treatment of diseases of the brain and the spinal cord has been relatively less than the improvement in our knowledge of the seat and nature of the diseases for which surgical intervention is useful and necessary. Correct diagnosis of these affections is still far to seek, and yet operative treatment in such a difficult field is often expected to yield equally good results as the relatively easier and simpler work of curing hernias or of removing abdominal tumors. In this connection Horsley considers both the palliative and the curative surgical procedures to be adopted, the details of these procedures, such as previous preparation, anesthesia, maintenance of the bodily temperature, etc. Although he at one time favored a combined anesthesia of morphin with chloroform, he now uses pure chloroform. Ether he regards inadmissible as an anesthetic in operations on the central nervous system. To prevent shock and to maintain the physiologic energy during these operations on the brain, the wound should be irrigated constantly, usually with a solution of sublimate, 1 to 10,000, or with saline solution at a temperature of 115. This will also arrest capillary and arterial hemorrhage. Venous bleeding and capillary oozing can be controlled by the inhalation of oxygen. As to the method of opening the skull, the bone should be divided with as little vertically applied force as possible and removed with the least possible pressure on the brain and dura. This can best be done by first removing a trephine disc, then marking with a large saw the area to be removed, and finally cutting away the bone with a large bone forceps, all traction being directed outward. Horsley says that the less drainage is employed the better, and consequently every effort should be made to close the skin wound as early as possible. In all these cases operations should be resorted to as early as possible and the tumor should be freely exposed and examined and extirpated with the surrounding tissue. If it can not be removed without undue interference with important or essential structures, there remains some possibility of its undergoing retrogression in a certain number of cases.

The Circulation Viewed from the Periphery.

Sir James Barr took the above as the subject of the address in medicine. Diseases of the heart most frequently arise from causes acting on the periphery and the man who studies the circulation with the aid of the stethoscope only, is a positive danger to society. The capillaries varying from 0.5 to 1 mm. in length and from 7 to 13 microns in diameter, have a blood pressure of from 50 to 2,000 mm. of water and a velocity of from 0.5 to 25 mm. per second. Attempts to arrive at their capacity or sectional area have given unreliable results, because of the complicated factors influencing the pressure and rate of flow. Barr estimates the velocity of the capillary circulation by pressure on the skin driving out the blood, and noting the time occupied in its return. The velocity of the flow and the pressure stand in an inverse relation to each other; the greater the obstruction to the outflow the greater the capillary pressure and the less velocity of the blood in them. If an obstruction to venous outflow is imposed, the pressure in the veins tends to approach but does not equal that in the capillaries, and the pressure in the capillaries approaches but does not equal that in the arteries. Gravity increases the pressure in the capillaries in a varying degree in different persons, but seldom to more than half the difference in the hydrostatic pressure. The velocity in the capillaries varies as the general blood pressure, but is diminished by contraction of the arterioles which supply the part. The blood in the capillaries becomes surcharged with carbon dioxid when the velocity is reduced below 1 mm. per second, giving a dusky hue to the skin; this is often more apparent in the upper extremities because the circulation is more active in the capillaries of the feet on account of gravity. Viscosity of the blood, normally five times that of distilled water, varies greatly, is increased by CO_2, diminished by high temperature, and is increased in many diseases and forms the chief obstacle to the flow of blood through the capillaries. The arterioles interpose an obstruction which reduces the effect of arterial pressure on the capillaries; hence the more the arterioles are contracted the less the pressure in the capillaries and *vice versa.* The regulation of the circulation by the vasomotor nerves saves the nerve centers of the brain from being completely depleted as happens to a rabbit with paralyzed vasomotor nerves when he is hung up by the ears. The varying pressure to which the walls of the capillaries are subject and the permeability of the vessel walls account, in the author's opinion, for the phenomena of transudation and absorption, without assuming a secretory activity on the part of the endothelia. Liquid is forced out near the arterial end where the pressure is high

Miscellany

Advertisers and the Gullible.—The Dutch member of the newly founded International Antiquackery Association, van Elk, tells the true story that an advertisement appeared in the papers stating that for 75 cents a powder would be sent which, if scattered on the waters of a stream or pond, would stock it with edible fish. A man sent the 75 cents for the powder, but his money was returned to him with the statement that the advertisement was inserted on a wager that no paper would accept such a nonsensical advertisement and that no one would be found foolish enough to respond to it if published. The letter added that the applicant was not the only one; he had been preceded by 256 others.

Experimental Arteriosclerosis and Iodin.—According to an item in the *Med. Klinik* for April 29, Koranyi recently reported at a scientific meeting at Budapest that he had been able to control arteriosclerosis. He injected 17 rabbits at two-day intervals with 0.15 c.c. of a standard preparation of suprarenal extract. A small amount of a preparation of iodin was injected at the same time, also intravenously. After about 9 injections the animals were killed. In 8 of the 9 animals who had not been injected with iodin changes were found in the aorta characteristic of the "adrenalin arteriosclerosis" first described by Josué. Only one of the animals was sound in this respect, while of the animals treated with iodin, 6 were sound, and merely slight evidences of the arteriosclerosis were found in the 2 others. It seems evident from this research that iodin has a favorable influence on the arteries, modifying the great fluctuations of the blood pressure which are probably the principal factor in the experimental arteriosclerosis.

Auto-Narcosis for the Wounded and Others in Severe Pain.—We learn that Prof. C. L. Schleich of Berlin has recently published a pamphlet entitled "Auto-narcosis for the Wounded in War and Peace"—"Die Selbstnarkose der Verwundeten in Krieg und Frieden." It describes a little contrivance which he thinks may prove very useful. A small aluminum case holds three small bottles, each containing a long cotton wad fastened to the cork and impregnated with 50 gm. of his anesthetic mixture. This consists of 2 parts ethyl chlorid, 4 parts chloroform and 12 parts ether, the whole having a boiling point at 38 C., the fumes thus being of the same tension as the air in the lungs. The stopper is drawn from one of the bottles and the fumes inhaled. Analgesia is immediate and is followed by profound sleep. He believes that this harmless method of auto-anesthesia or its equivalent is destined to supplant morphin hypodermics. The appliances should be kept on hand in mines, factories and elsewhere, and the anesthetic be given before transporting the wounded persons.

Photographing the Dead for Identification.—The London *Lancet* for May 5 states that the coroner at two recent inquests commented on the unsatisfactory character of the photographs of the unidentified dead taken by the police authorities. It adds that Dr. Minovici has contributed a valuable communication to this subject from his experience as director of the Medicolegal Institute of Bucharest. He describes his methods in an article published in the *Archives d'Anthropologie Criminelle* for Nov. 15, 1904. He substitutes artificial eyes, and gives a natural appearance to the lids by means of lead foil or by pinning them with a fine pin to the eyeball. The jaws are drawn together with threads, and the face drawn to a natural expression by an arrangement of pins, evacuating accumulations of gases by incision in the scalp or mouth. He gives photographs of the various steps of this preparation of the corpse for photography, and states that by this means he was successful in one case in which the body had been immersed in water for six weeks, the identity being finally established by the photograph.

Injurious Influence of Night Work on the Composition of the Blood.—Gardenghi has been conducting research which apparently shows that light is as indispensable to human beings as to plants for normal growth and development. There seems to be a deficiency in the assimilation of iron under the influence of the lack of daylight, with consequent deficient formation of hemoglobin. Light seems to be required for normal production of hemoglobin the same as for the production of chlorophyll in plants. He presented the conclusions of his research at the recent International Congress for Professional Affections at Milan, dwelling especially on the harmfulness of night work. Long series of examinations of bakers at Parma, his home, showed that while the proportions of the blood corpuscles were about normal, the percentage of hemoglobin was very much below par in those who worked exclusively during the night. His article is reproduced in German in the *Wien. klin.-therap. Wochschr.*, xiii, 697.

Quackery.—In the address to the graduates at Edinburgh university, an abstract of which appears in the *Medical Press*, August 8, Thomas Annandale, professor of surgery, said that two theories have been suggested to explain why primitive man first had recourse to internal remedies for the cure of disease, the one being that it was accidental and the other that it was in imitation of the lower animals. He referred to Pliny's account of the origin of venesection that the hippopotamus, having become too fat and unwieldly through overeating, thrust his nose against a sharp-pointed reed, and when he had drawn sufficient blood closed the wound with clay. He said that probably the first special treatment of disease was due to the Egyptians or Chaldeans; from them the Greeks obtained their knowledge, and Cheiron was the first to instruct his countrymen, among them Esculapius, who is credited with being the originator of medicine as a distinct profession. Between the days Esculapius, who flourished in 1200 B.C., and those of Hippocrates, 400 years later, medicine and myth are inextricably intermingled; the practice of the art seems to have been in the hands of a priesthood, who worshiped in temples devoted to Esculapius as the god of physic. With the writings of Hippocrates a new era dawned, for they show a marvelous knowledge of injuries and disease and contain methods of treatment founded on sound principles. As knowledge and civilization advanced, although improvements in the art of medicine took place, quackery continued rampant. The credulity which the study of quackery discovers almost approaches monomania or insanity. This credulity is explained by the fact that in all times there have been men and women of strong personalities and unlimited self-assertion who dominate their fellow creatures and exercise a power for evil as well as good, and it is also explained by the natural tendency of a patient with a chronic illness to seek help from any source. He mentioned the exponents of quackery in the past. There was Buley, for instance, in the days of Edward VI, who gave roasted rats as remedies to sick children; touching for the king's evil, which attained its height in the reign of Charles II; the quack oculists of Queen Anne, who suffered from weak eyes and was treated by William Reade, a tailor, and Roger Grant, a cobbler and Anabaptist preacher. Mesmer flourished in 1776, and a commission of the French Academy of Science was deputed by the king to investigate his claims. Among noted quacks of the past, Annandale said, were Katterfelto, who wandered through the country with a caravan full of black cats and was finally condemned as a vagabond by the mayor of Shrewsbury; a Dr. Graham, who sold an elixir of life to any one who would pay him $5,000 for it, and conducted a Temple of Health, in which Lady Hamilton, Lord Nelson's goddess, took part in musical performances. Again, there was the fat, ugly, tippling Mrs. Mapp, with her carriage and four, who was esteemed as a bone-setter and known popularly as "Crazy Sally of Epsom." A very notorious quack was St. John Long, son of an Irish basketmaker, who acquired fame as a healer. His house in Harley Street was flocked to by the rank and fashion of the day, who were treated by inhaling some mixture through a tube. The street was often blocked by his patients' carriages; he was received into the best society; it is said that he made $67,000 in one year. He ended by being tried for manslaughter at the Old Bailey, but escaped with a fine of $1,250. Faith cures and cures acting on the imagination have thus flourished from very early times, Annandale said, and more recently a faith cure under the name of Christian Science has sprung up. In this history is repeating itself. In ancient and more modern days so-called faith cures have been carried out by the aid of ceremonies and incantations and the erection of temples to aid the imagination.

mainland and what the sea furnishes. Several negro women, the most ugly and vicious-looking that we have seen so far, who were selling palm wine, did the best business. The wine in large earthen jars was still fermenting and bubbling. Two cents bought a gourdbowlful, holding about a quart. Two such doses make the black happy for the balance of the day. The behavior of the Amazons who dispensed this stuff was enough to show that they had done their share in emptying their vessels. We tasted this palm toddy. It was cool and pleasant to the taste, slightly sour and had some of the pungency of dry champagne. There were fish, fresh and fried, bananas, thin, narrow strips of bread fresh from the stove, served hot on banana leaves, cocoanuts, papaya, manihot roots, raw and boiled, several kinds of capsicum, small bundles of split firewood, etc., all articles for which only the natives have use. What little is left of the island outside of the city is a sandy desert.

The sight that I presume every visitor who lands here goes to see is the old fort of St. Sebastian. It is this ancient fort, with its grim, high walls blackened with age, which is seen first when the city comes in view. The building of this fort dates to the time of Da Gama, when he sailed along the east coast of Africa in search of a new waterway to East India. The fort is built on a narrow spit of the island, covering its entire width, and the thick, solid walls rise from the sea on three sides. It is kept in good repair and now serves as a barrack for the soldiers. The walls rise high above the inner even court, where the black soldiers are drilled in the art of war. On the top of the rampart facing the sea the portholes are occupied by ancient cannons of prodigious size, mounted on carriages with rickety wooden wheels. These fearful engines of war probably have never spoken, but were ready centuries ago to spit fire and destruction had any foreign power made an attempt to gain possession of the little island. This ancient citadel, with its historic guns, would be helpless against a single modern battleship, but it has been respected in the past, and may well be proud to have outlived other more formidable strongholds over which the flag of many a conqueror has floated since their foundations were laid. The veteran fortress shows only one scar, and that was made by an accidental explosion of dynamite and is now being repaired with the utmost care.

The Roman Catholic church rules here supreme. The cathedral is a very modest church and the other two churches show no greater pretensions. The church has been prudent in the expenditure of money. Schools had to be erected and maintained. In the yard of one of these schools we saw the black children at play after the morning lessons were over, and they were indeed a cheerful, happy lot.

Portuguese and natives live on the best of terms throughout this possession. There is no conflict nor even manifest dissatisfaction here. The government treats its black subjects leniently and with much consideration. Experience has shown that the negro can be led, but not forced, to do a thing which comes in conflict with his own ideas of right and justice; he is a lamb when led, a mule when forced. Only two Germans and nine Englishmen live in the city and only a very few East Indians and Arabs. Mozambique has its own postage stamps, and the money in circulation is coined for Portuguese East Africa.

MOZAMBIQUE MILITARY AND CIVIL HOSPITAL.

I have never been in a colony or protectorate where the native sick are treated with so much consideration and are taken care of so well as in Portuguese East Africa. The colony has no separate hospitals for Europeans, as in British and in German East Africa, but white and black live under the same roof and receive the same care. We miss here the superb, costly buildings set aside exclusively for the care of Europeans, such as I have described in speaking of British East Africa and German East Africa. Of all nations owning or protecting foreign lands, Portugal has had the longest experience and has learned how to treat alien subjects without causing friction. The sentiments of the people are considered in formulating rules for their government. Perhaps the most important secret of Portuguese peaceful colonial rule is found in the fact that the line of division between the officers and the people of the home government and the blacks is not as sharply drawn as in the colonies of other nations. It is the conspicuous preference given to the whites that stings the blacks, the rightful owners of the soil. The Portuguese have learned this by a long experience and shape their rules accordingly.

I can give no more striking example of Portugal's lenient foreign policy than by a brief description of the Mozambique Military and Civil Hospital, which answers to the construction and administration of every other government hospital in Portuguese East Africa, of which there are several. In the first place, these hospitals are built and, at least in part, maintained by the government, and are in charge of Portuguese military surgeons, especially trained for their manifold functions. In the second place, the sick in the colony, white and black, officers, government officials, soldiers, policemen, rich and poor, educated and ignorant, old and young, men, women and children, are under the same administration. While the whites are given preferences, these do not stand out in the eyes of the natives in such sharp lines as in the hospitals of most of the other colonies. The same doctor who treats the whites attends to the blacks; the same sisters who nurse the Europeans take care of the natives. The difference, if any, is in degree, not in kind, and it is considerations like these that the negro knows how to appreciate.

The hospital was built twenty-five years ago, and at that time it would have compared well with most of the hospitals of Europe and America in construction and equipment. Its architecture is decidedly Spanish in style. Like all other substantial houses on the coast of Africa, it is built of rough stones of coral rock, with a heavy inside and outside coating of cement. The two main buildings are two stories high and serve for private rooms of patients of the first class, small wards for the second class, directors' apartments, pharmacy, storerooms, chapel and dormitory for the sisters. The large wards for patients of the third class and all charity cases are in one-story pavilions, the blacks in separate wards. The first-class patients pay $2 per day, the second-class 75 cents and the third-class 25 cents. Light and air flood every room of the handsome, well-arranged complex of buildings, which on one side face the principal street of the city and park and on the other the harbor. As the city of Mozambique must rely on rain for its water supply, each house has its own cistern. The hospital has two immense underground cisterns, with a total capacity of 600,000 tons, which furnish an abundance of pure, cool drinking water. These cisterns are located between the pavilions. The spaces between the main buildings and the wings are paved with flat stones and are kept as clean as the mosaic tile floors in the interior of the buildings. The hospital has 200 beds, and during the rainy season, when malaria is most prevalent, its full capacity is heavily taxed, but at the present time the number of patients is only eighty. The pharmacy is in charge of a competent druggist and is well stocked, and the two large storerooms are well supplied with medicines, dressing materials, bedding, etc. The operating room is small but well constructed and equipped for modern surgical work. Very little surgery is done here, as in all other East African hospitals, on an average not more than two operations a day, and most of these are minor operations. A Roentgen apparatus has recently arrived and will be put in operation as soon as electric power can be secured, and then it will be the first one to be employed on the East Coast of Africa. Dr. Francisco Maria do Amaral is the director of the hospital and is assisted by three other military surgeons. He speaks English fluently and has kept pace with the modern progress in medicine and surgery. He took great pains in explaining the details of the hospital work and in showing the interesting cases then under treatment.

Eight Catholic sisters have charge of the nursing and they are assisted by orderlies and native helpers. The average number of patients during the year is about 2,000. The patients come from all parts of the province of Mozambique. Dr. Amaral has been stationed here for a long time and has never seen a case either of carcinoma or appendicitis in the black. The same holds true of the Eskimos of the far north, as I

BERIBERI.

This disease was observed 18 times during the year. Lorenzo Marques furnished 15 cases, Mozambique 1 and Chile 2. Of this number, 5 died.

RHEUMATISM.

Of this disease there are recorded 370 cases, 230 acute and 120 chronic, with a mortality of 4, 2 from the acute and 2 from the chronic form of the disease.

We miss in this enumeration of diseases carcinoma, with the exception, perhaps, of a doubtful case, also appendicitis and typhoid fever. Strangely enough, typhoid fever has not as yet gained a foothold on the soil of the east coast of Africa, although the sanitary conditions in many places are such as would seem favorable to the growth and spread of the bacillus of the disease. Neither is there mention made of the most common diseases of childhood: measles, diphtheria, scarlatina and whooping-cough. Twelve cases of cerebrospinal meningitis were observed, with a mortality of 5. Considering the severity of the climate, the prevalence of malaria and its many complications and the doubtful water supply of the people living in the interior, the general mortality could not be called excessive. The national vice of laziness and the absence of manufacturing establishments of any importance account for the small number of injuries, only 449 cases.

BEIRA.

Beira, at the mouth of the Pungwe River and a short distance south from the delta of the great Zambesi River, is the most important port of Portuguese East Africa. The little city is located on a narrow, sandy strip of land between the mouth of the Pungwe River, which serves as an excellent harbor, and Mazangzani Bay. The terminus of the Rhodesia Railroad here adds much to the commercial and shipping importance of the city. Most of the houses are solid two-story brick and cement buildings, with tile or corrugated iron roofs. There are only two or three horse vehicles here. The principal street bisects the city and has in the middle a narrow-gauge track of the man trolley cars, a great convenience for getting about the far-spun-out city and for the transfer of freight. Most of the professional and business men have their own private car and their own man to push it. Two persons can sit comfortably side by side, and in case of need a third can be sandwiched in between. There are only a few short sidewalks in the city, so that most of the walking must be done by wading ankle-deep in the loose, hot sand. At the time of our visit the heat was very oppressive. There are a few large stores, in which almost everything is kept which is most needed, but at prices which stun the visitor. Among the several hotels the Savoy and Queen's Hotel are the best. The table of the former, for such a place as this, is excellent, and the rooms are large and airy. A bank, several steamship offices and the railway office handle the bulk of the money. The prison, in the heart of the business part of the city, is a most unique building. It is small and has all the appearances of a neat chapel if it were not for the strong iron bars of the high, narrow and numerous windows. The city is only ten years old. The next city on the coast south from here, Sofula, was for several hundred years the port. The good harbor here made it necessary to transfer business and shipping to this place. A few kinds of hardy trees, cocoa palms, eucalyptus, acacia, wild almond, etc., have been planted and seem to thrive in this dry, hot, sandy soil. Most of the natives are kaffirs, black as coal and fine specimens of physical development and muscular strength. Most of the laborers wore nothing but a loin cloth, and this in most instances was none too wide.

Beira has an unenviable reputation as a fever nest. Mr. Bryce, who visited this place before the railroad was completed, made the statement that no white man could remain three consecutive days anywhere between Beira and the inland mountain plateau and escape an attack of fever. All the white people who have lived here for several years have had their good share of malaria. I examined a number of negro children and they all had the prominent abdomen seen in children living in malarial districts, and in all of them the enlarged spleen could be felt several inches below the costal arch. All the white women I saw were pale, emaciated and evidently much enfeebled, as was shown by their drawn faces and languid walk. Their little children were in the same condition. Several of the sisters in the hospital were very anemic, poor in flesh and none too strong for the arduous duties in care of the sick in their charge.

Beira is one of the hottest places on the coast. The hottest months are December and January. At this time the thermometer not infrequently registers 120 F. in the shade, and I was told that eggs placed on the hot sand and exposed to the burning rays of the sun were cooked hard in a short time. Throughout the year it is disagreeably warm from 10 o'clock in the morning until 4 in the afternoon, and during this time the people remain in their houses and very little work, if any, is done. Even the postoffice officials have their midday siesta. The mealtimes are so arranged that they do not interfere with the working hours. The first plain breakfast early in the morning is followed by a second one at 11:30 a.m., which is a substantial meal. Dinner is served late in the evening.

BEIRA GOVERNMENT HOSPITAL.

Beira has only one hospital, which was built and is maintained at government expense. It is beautifully located in park-like grounds and faces the principal street on one side and on the other side the bay. The hospital was built ten years ago at a cost of $25,000 and has room for sixty patients. At present, the coolest and healthiest season of the year, the number of patients does not exceed thirty, and most of these are suffering from malaria. The government physician, Dr. José Aranjo de Lacerda, is in charge of the hospital and the nursing is under the care of five Sisters of St. Francis. The hospital consists of two one-story brick and cement barracks, one for the whites and the other for the blacks. The cots in the latter building are the narrowest I have ever seen, hardly eighteen inches in width. The framework is made of iron bars, on which a piece of canvas is stretched. Each cot is supplied with two white sheets and a pillow, and the patients on these, the narrowest of all beds, appeared to be comfortable. Simple and plain as these beds are, they must seem a luxury to the blacks, who know no softer bed than a mat on the bare ground. In the cottage for the whites are a number of plainly furnished but very comfortable private rooms, for which a charge of $5 a day is made. In the little wards the second-class patients pay $1 a day. Few of the negroes are able to pay anything, and as this class of patients during the year is large they become a heavy tax on the financial resources of the hospital.

I saw and examined here patients suffering from malaria in all its multitudinous forms. In the acute form the temperature curves were nearly the same in all cases. A chill, followed by a temperature of 40.8 C., then under quinin treatment a speedy fall to normal. Dr. Lacerda, like Dr. Amaral, relies largely on the subcutaneous use of quinin in doses of seven and one-half to fifteen grains, administered once or twice during twenty-four hours. In some cases quinin is given at the same time by the mouth, and to prevent its being ejected by vomiting it is mixed with pulverized gentian. If, as is often the case, a light icterus makes its appearance, three grains of calomel are given, followed by a saline cathartic. In the beginning of the attack evaporating camphorated lotions are employed to reduce the high temperature, and phenacetin is given to relieve the intense headache. In chronic cases arsenic is frequently used in combination with quinin. In the pernicious form of malaria the system is saturated as quickly as possible with quinin, given subcutaneously and by the stomach, so that the patient receives at least forty-five grains during the first twenty-four hours. One case of blackwater fever was under treatment and well on the way to recovery. Beside malaria, I found in the ward for the natives a case of advanced pulmonary tuberculosis, parenchymatous mammitis in a syphilitic woman, tropical abscess in a boy about 12 years old and a case of chronic dysentery. In front of this ward we saw squatting on the sand an old negro, a mere skeleton, evidently the subject of some mental derangement. He refused to eat rice, meat and other nutritious articles of the hospital diet, but made his evening meal of black coffee and a piece of bread, which he tore in pieces and

total number of candidates examined was 16, of whom 11 passed and 5 failed, including *one undergraduate* and one osteopath. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
University of Colorado	(1906)	72.3, 79.3, 81
College of P. & S., Los Angeles	(1905)	74.1
Denver Homeo. Med. Coll.	(1906)	72.4, 73, 76.1
Northwestern Univ. Med. School	(1901)	78.7
Eclectic Med. Inst., Cincinnati	(1906)	72.5
Jefferson Med. Coll.	(1905)	70
Royal University of Padua	(1884)	71.2

FAILED.

College.	Year. Grad.	Per Cent.
Kentucky University	(1903)	66
Barnes Med. Coll.	(1905)	65.9
Missouri Med. Coll.	(1888)	48.7

Besides the following who were registered on presentation of acceptable credentials, there were also registered two old practitioners, one of whom was an army surgeon during the Civil War:

Cooper Medical College	(1894)
University of Colorado	(10, 1906)
Denver and Gross College of Medicine	(1, 1905), (18, 1906)
College of P. and S. Chicago	(1, 1904), (2, 1905)
Northwestern University Medical School	(1906)
Rush Medical College	(1888), (1892)
Bennett College of Eclectic Med. and Surg.	(1882)
College of P. and S., Keokuk	(1887), (1904)
Tulane University	(1901)
Maryland Medical College	(1905)
College of P. and S., Boston	(1894)
Harvard University Medical School	(1899)
University of Michigan	(1904)
University of Minnesota	(1904)
University Med. Coll., Kansas City	(1891), (1906)
Ensworth Medical College	(1897)
Northwestern Medical College, St. Joseph	(1892)
Barnes Medical College	(1893)
Niagara University	(1890)
New York Med. Coll. and Hospital for Women	(1894)
Albany Medical College	(1881)
Western Reserve University	(1883), (1904)
Eclectic Medical Institute	(1886), (1893)
University of the South	(1900)
University of Vermont	(1889)
Ecolé de Med. de Paris	(1904)

The following were rejected on account of not having acceptable credentials:

Northwestern University Medical School	(1897)
Chattanooga Medical College	(1903)
Fifth Medical College, Nagasaki, Japan	(1897)

Indian Territory July Report.—Dr. M. F. Williams, secretary of the Board of Medical Examiners of the Western District, sends us a list of individuals registered on their credentials without examination, at the meeting held at Muskogee, July 2, 1906. The following colleges were represented:

REGISTERED.

Howard University	(1904)
Georgia College of Eclectic Medicine and Surgery	(1898)
Northwestern University Medical School	(1905)
National Medical University	(1903)
Indiana Medical College (Purdue University)	(1906)
Keokuk Medical College	(1900)
University of Louisville	(1894), (2, 1906)
Maryland Medical College	(1905)
Washington University, St. Louis	(1906)
College of P. and S., St. Louis	(3, 1906)
Barnes Medical College	(3, 1906)
Kansas City Medical College	(1901)
Missouri Medical College	(1884), (1906)
University Medical College, Kansas City	(1905)
Memphis Hosp. Med. Coll.	(1901), (1906)
Meharry Medical College	(1898), (1905), (5, 1906)

REJECTED.

Gate City Medical College*	(1905)

* School not recognized.

Iowa May and June Reports.—Dr. J. F. Kennedy, secretary of the Iowa State Board of Medical Examiners, reports the written examinations held at Keokuk, Sioux City, Iowa City and Des Moines, May 23-24, May 31-June 2, June 6-8 and June 11-13, 1906, respectively. The number of subjects examined *in* was 8; total number of questions asked, 100; percentage required to pass, 75.

At the examination held at Keokuk the total number of candidates examined was 52, of whom 43 passed and 9 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Keokuk Med. Coll. of P. & S. (1905) 75; (1906) the grade of 77 was reached by *two*, 78 by six, 79 by three, 80 by two, 81 by one, 82 by six, 83 and 84 by five each, 85 by three, 86 by four, 87 by one and 88 by four.		

FAILED.

College.	Year. Grad.	Per Cent.
Keokuk Med. Coll. of P. & S.	(1906)	60, 65, 67, 72, 73, 73, 74, 74
College of P. & S., St. Louis	(1906)	60

At the examination held at Sioux City the total number of candidates examined was 17, of whom 14 passed and 3 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Sioux City Coll. of Med. (1906) the grades of 75 and 79 were reached by *one* each, 80 by five and 82, 83, 85 and 86 each by one each.		
Illinois Med. Coll.	(1904)	75
Creighton Med. Coll.	(1906)	86
New York *University*	(1893)	91

FAILED.

College.	Year. Grad.	Per Cent.
Sioux City Coll. of Med.	(1906)	70, 73, 73

At the examination held at Iowa City the total number of candidates examined was 59, all of whom passed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
University of Iowa (1906) the grade of 77 was reached by three, 78 by one, 79 by three, 80 and 81 by four each, 82 and 83 by seven each, 84 by five, 85 by four, 86 by six, 87 by eight, 88 by one, 89 by two and 90, 92 and 93 by one each.		
University of Louisville	(1906)	86

At the examination held at Des Moines the total number of candidates examined was 30, of whom 27 passed and 3 failed. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Yale University	(1903)	86
Drake University	(1906)	79, 82, 83, 85, 86, 87, 88, 89, 91
Bennett Med. Coll. Eclec., Chicago	(1906)	85
College of P. & S., Chicago	(1906)	81, 82, 83, 88
Northwestern Univ. *Med. School*	*(1904)*	90
Rush Med. Coll.	(1902)	81
University of Michigan	(1904)	90
Creighton Med. Coll.	(1906)	76, 78, 79, 81, 81, 85
Jefferson Med. Coll.	(1906)	84
Meharry Med. Coll.	(1902)	75

† Became Med. Dept. Washington University in 1891

Medical Organization

Georgia.

WASHINGTON COUNTY MEDICAL SOCIETY.—With the aid of Dr. W. W. Pilcher, Warrenton, councilor for the Tenth district, the physicians of Washington County met at Sandersville, organized a county medical society *on the standard plan* and elected the following officers: Dr. David E. McMaster, Tennille, president; Dr. Oscar L. Rodgers, Sandersville, vice-president; Dr. Henry A. Hermann, Sandersville, secretary and treasurer, and Drs. Eugene A. Harris, Sandersville; Julian H. Evans, Davisborough, and *D. L. Cheatham*, Sandersville, censors.

To control the choreiform movements in some of these cases Shoemaker recommends the administration of cimicifuga racemosa, giving the fluidextract in 5 minim doses (.20), three times a day after food. The dose should be increased daily until full physiologic effects are produced. The symptoms thus produced are vertigo, intense headache and nausea. This preparation, according to Shoemaker, not only ameliorates the symptoms by lessening the reflex activity in the spinal cord, but when prescribed in small doses it aids and stimulates digestion by awakening the action of the glands along the alimentary tract.

In cases in which the menstrual flow has been checked this preparation is also of value. It serves as a stimulant to the heart and general circulation similarly to digitalis. As an efficient form of medication to be used along with cimicifuga as a synerguist, the following combination is recommended:

R.	Ext. hyoscyami			
	Ext. cannabis indicæ, āā	gr. ¼		015
	Camphoræ monobromatis	gr. v		30
	Olei theobromatis, q. s.			

M. Ft. suppository No. i. Sig.: One suppository inserted into the rectum three times daily.

Salicylic Acid.

IN PRURITUS.

The following combination containing salicylic acid is recommended by Ringer in the treatment of pruritus of the vulva and anus:

℞.	Acidi salicylici	ʒii	8	
	Olei theobromæ	ʒvi	24	
	Olei myristicæ	f. ʒii	8	

M. Ft. unguentum. Sig.: Apply locally to the affected parts.

FOR CORNS.

In the treatment of corns Hare recommends the following combination:

℞.	Acidi salicylici	gr. xxx	2	
	Ext. cannabis ind.	gr. v		30
	Collodii	f. ℥ss	15	

M. Sig.: Apply with a brush until a good coat is formed.

FOR WORMS.

To get rid of thread worms or seat worms the following injection by the bowel is recommended:

℞.	Acidi salicylici			
	Sodii boratis, āā	ʒss	2	
	Aquæ	Oi	500	

M. Sig.: Warm gently and inject into the bowels.

For a child the amount should be reduced one-half in strength.

FOR BROMIDROSIS.

In the treatment of bromidrosis of the feet associated with fetor, salicylic acid is of service, dusted over the parts, or the following powder may be used:

R.	Acidi salicylici			
	Pulv. amyli, āā	℥ss	15	

M. Sig.: Apply locally to the feet.

FOR ECZEMA.

In eczema of the face and hands, when the eczema is moist, the following combination is advised, applied locally:

R.	Acidi salicylici	gr. v-x		30-.65
	Pulv. amyli			
	Pulv. zinci oxidi, āā	ʒii	8	
	Petrolati, liq.	f. ℥ss	15	

M. Ft. unguentum. Sig.: Apply locally.

FOR CHANCRES.

In the treatment of soft chancres and venereal sores salicylic acid is sometimes of value:

R.	Acidi salicylici	gr. xx	1	20
	Alcoholis	gtt. xlv	3	
	Adipis benzoinati	℥ii	60	

M. Sig.: Apply locally.

Or,

℞.	Acidi salicylici	gr. xv	1	
	Pulv. amyli vel cretæ	ʒii	8	

M. Sig: Apply locally.

Incompatibility of Potassium Iodid.

In speaking of the frequency of prescribing preparations which are incompatible, our attention is called to an article by Jennings in *London Hosp. Gazette*, who states that potassium iodid, when prescribed with other preparations, frequently causes trouble. This preparation, in a simple solution, when exposed to the light, often liberates iodin.

Potassium iodid should never be prescribed with ferric chlorid as the latter preparation is rapidly decomposed, forming ferrous iodid and free iodin. According to Jennings, however, the two scale preparations, iron and ammonium citrate, and tartarized iron are compatible with potassium iodid.

A crystalline precipitate of strychnia iodid is formed when strychnin hydrochlorid is mixed with a solution of potassium iodid, and in concentrated solutions a precipitate may be formed immediately.

Spirits of nitrous ether contains a small amount of free nitrous acid and a free acid where combined with potassium iodid may liberate iodin. In the same way sodium nitrite may produce like results.

The following combination serves as an example of this incompatibility:

℞.	Sodii nitritis	gr. ii		12
	Potassii iodidi	gr. v		30
	Caffeinæ citratis	gr. x		65
	Aquæ	f. ℥i	30	

M. Sig.: As directed.

In the foregoing free iodin will be liberated.

Caffein citrate in the above, being a very weak base, is separated into the alkaloid caffein and citric acid when mixed with water, and the latter decomposes the sodium nitrite, forming the nitrous acid.

Bismuth oxynitrate is *incompatible with potassium iodid*, when the two are mixed with water, producing a yellowish color, changing to a brick color later. This is a case of double decomposition, no free iodin being produced.

Ocular Eczema.

In the treatment of ocular eczema, which is most commonly a disease of childhood, and which forms 21 per cent. of all the diseases of childhood, Frederick Krauss in *Med. Record* states that three phases of treatment should be considered: 1. Hygienic and dietetic; 2, medicinal; 3, local. The hygienic treatment, according to Krauss, should consist in fresh air, wholesome, nourishing food, the abstinence from sweets, pastry of all sorts, and in severe cases absolute rest in bed. The room should be so situated as to exclude the direct sun's rays, but should admit plenty of light. A dark room should never be permitted, but the eyes should be protected from strong light by tinted lenses, a shade or a bandage over the eyes if the discharge is not too great.

The diet should consist of milk properly modified, eggs, fresh cooked meat or raw meat juice, orange juice, stewed fruits, etc., omitting puddings and pies and all pastries. Sugar corn, bananas, peanuts and pretzels should be especially excluded from the diet.

Salt water baths daily are recommended, given warm at bedtime. The medical treatment consists of tonics and alteratives with the relief of constipation.

Krauss recommends the following combination as a tonic and alterative:

℞.	Syr. ferri iodidi	ʒiv	15	
	Syr. acidi hydriodici	℥i	30	
	Syr. hypophos. co. (N. F.)	℥iss	45	

M. Sig.: One teaspoonful in water before each meal. In children from twelve to fifteen years of age two teaspoonfuls may be given.

Attention must also be directed to eczema of other parts of the body, especially to the nares, for which an alkaline cleansing wash, followed by a bland ointment, such as the unguentum acidi borici is advised.

The local treatment to be carried out in the milder cases of eczema of the conjunctiva is a simple boric acid wash, with the

wilfully neglecting to furnish his wife, then pregnant and about to be delivered of a child, with such care and attention as were necessary during her confinement in childbirth, thereby causing her death. But it was manifest from the evidence that the confinement came five days sooner than they expected it; that the wife, having read, besides other books, "Tokology," and corresponded with its author, had resolved to do without the services of a physician in her confinement, and had influenced her husband to adopt her opinion that the services of a physician would be unnecessary at such a time; that during her labor he dutifully remained with her, and assisted her to the best of his ability, and as she directed him; that when he discovered her peril he called in two women living in the same house to assist him in caring for both mother and babe; and that on the suggestion of one of them he immediately, and over his wife's objection, sent for a competent physician to minister to her, and that the latter, in spite of her protestations, apparently did what he could, and all she would allow him to do, to relieve her, but failed to preserve her life. In view of these facts, and the further facts that the husband was an affectionate one, and had never appeared indifferent to his wife or neglectful of any conjugal duty, and that in failing to earlier call in a physician he acted in good faith and at her request, though he doubtless erred in so doing, this court fails to find any just or reasonable ground for the verdict of the jury; indeed, it thinks it wholly without support from the evidence.

Those of us who reverence the medical profession and implicitly trust the learning and skill of the family physician, the court goes on to say, may be disposed to attribute to ignorance or prejudice such a lack of confidence in that profession as was manifested by this wife, and wonder that the husband, in the face of such a crisis as confronted them, should have allowed himself to be influenced to trust to Nature's laws, or supernatural aid, rather than medical skill; but the fact remains that there are many who reject, as they did, both medicine and surgery for other means, or supposed means, of healing, and are perfectly sincere in doing so. We may concede that the wife made a grievous mistake in adhering to her purpose of rejecting medical aid, yet in view of the suffering, and, in the end, death, to which she subjected herself, her sincerity can not be doubted. And certainly there was nothing in the evidence which tended to prove that the husband, though making the same mistake, was any less sincere than she, unless it was the fact of his sending for a physician after the birth of the child. This act, however, appeared from the evidence to have resulted more from his desire to leave nothing undone for her relief than from a belief that benefit would result to the wife from the physician's presence or treatment. In any event, it was the very opposite of neglect, and should go to the credit, instead of the debit, side in the husband's accounting for the offense charged in the indictment. One cannot be said in any manner to neglect or refuse to perform a duty unless he has knowledge of the condition of things which require performance at his hands.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

2 *Insane Lovers. J. W. Stevens, Amityville, L. I.
3 Medical Inspection in Public Schools. I. C. Philbrick, Lincoln, Neb.
4 *Removal of an Intraligamentary Cyst and Bilateral Oöphorectomy During Early Pregnancy Without Interrupting Gestation. A. Brothers, New York.
5 *Contribution to the Etiology of Otitis Media Acuta Suppurativa Post Morbillos. G. Baar, Portland, Ore.

2. Insane Lovers.—Stevens calls attention to this subject as one of much importance to the general practitioner who first sees these cases. They are not uncommon in asylums and in neurologic practice. The patient may seem clear and rational on all other subjects, so that for some time he or she is considered entirely sane. The maniacal, insane lovers differ in certain prominent features from those of the paranoid class. In the *former group* the origin of this love is always to be traced to the abnormal sexual excitement, increased susceptibility to stimuli, facilitated release of impulses, and the lack of the restraining influence of the ethical sensibilities in the presence of elation and sense of well-being. At the beginning of this condition delusions and hallucinations are nearly always absent. In the paranoid case this love is only a part of a progressive and systematized delusional state. A strangely erotic element is not necessarily present. The maniacal patient often recognizes the abnormal nature of her impulses, while the paranoiac never does. The paranoiac is practically always monogamous, the maniacal often polygamous. In the latter the love disappears with the subsidence of the active symptoms of the individual attack, while in the former it remains throughout life. These patients should be carefully looked out for, not only for their own sake, but for the sake of their victims.

4. Bilateral Oöphorectomy and Removal of Intraligamentary Cyst.—Brothers operated in a case of this kind. The patient was seven weeks pregnant. The tumor lay quite low in the cul-de-sac of Douglas. Laparatomy was performed through a suprapubic transverse incision. The intraligamentary cyst was found on the right side, behind the uterus, and was removed in one mass with the closely connected Fallopian tube and cystic ovary. The ovary of the left side was found enlarged and microcystic. This ovary was exsected. Convalescence was uninterrupted, and the patient was delivered at term of a healthy child.

5. Etiology of Otitis Media Suppurativa Post Morbillos.—Baar reports the history of five children in the same family who were attacked with measles. In all of them there appeared an acute suppurative otitis media. In three of these children the mastoid process, the antrum and the cranial cavity had to be opened on account of alarming cerebral symptoms which appeared in spite of previous painstaking antiphlogistic and antiseptic treatment, poultices and drainage after careful irrigation of the exterior auditory meatus with warm solutions of borax or instillation with peroxid of hydrogen and drying. Baar declares that the appearance of purulent inflammation of the middle ear at the end of the second week of illness seems to speak very much against the universal view that the measles otitides are caused by the primary exanthem. The pus taken from the depth of the exterior meatus, as well as from the antrum, mastoid process, and extradural abscesses, contained the same staphylococcus.

6. The Gonioscope; New Ophthalmotrope.—Shute's device is constructed on the same principle as Landolt's, but differs from the latter in its simplicity, and in the case with which it can be constructed by any one out of very simple materials, such as an india-rubber ball, a hat pin and a tobacco box. It also differs from Landolt's apparatus in the fact that the rubber ball can be so easily painted, or marked with ink and made to serve as a model of an eyeball, instead of looking like a mere frame work of rings as does Landolt's; it also has the great merit of concentrating the attention of the student on a single axis at a time instead of distracting his attention by the presence of a number of very different axes. It can be made to show the rotation of the eye about axes in Listing's plane, thus giving lessons in physiology; or it can represent movements of the eyeball about axes perpendicular to individual muscle planes and thus out of Listing's plane so that the pathology of ocular motility can be investigated with the greatest accuracy. It readily permits also a study of ocular rotations under the influence of internal and external recti when attached to the eyeball, either too high or too low. Lastly, it differs from Landolt's instrument, in that it was primarily constructed for the purpose of demonstrating the necessity of diversity, instead of community of axes for the obliques on the one hand, and the superior and inferior recti on the other hand. In short, the instrument differs from all others, Shute states, in its extreme simplicity, flexibility and adaptability for demonstrating all the known ocular rotations on sound physiologic principles. The reader is referred to the original article for a complete description of the apparatus and the method of its use.

15 *Two Cases of Gastrosuccorrhea or Gastric Hypersecretion Associated with Atrophic Cirrhosis of the Liver. H. F. Hewes. Boston.
16 *Serum Treatment of Exophthalmic Goiter. G. A. Waterman, Boston.
17 Introduction to the Study of the Fundamental Cause of Splanchnoptosis—Abdominal Incompetence. A. C. Victor, Boston.
18 Incontinence of Urine. C. G. Kerley, New York.

15. **Gastrosuccorrhea Associated with Atrophic Cirrhosis of Liver.**—The special points of interest in connection with the few cases reported by Hewes are the following: The cases represented, in their special symptomatology, the history of the symptoms and the character of the findings revealed by the examination of the contents of the stomach, typical cases of gastrosuccorrhea, one of continuous hypersecretion, the other of intermittent or periodic hypersecretion; and this stomach symptomatology represented, at the time the cases first came under observation, the prominent and only definite symptoms present. The special pathologic conditions of the stomach, with which hypersecretion such as was present in these cases is ordinarily associated, that is, which most frequently prove to be the primary causes of hypersecretion, gastrectasis, or ulcer of the stomach, were not present in these cases. This fact was proven in the first case, that of continuous hypersecretion, by the findings at autopsy in addition to the results of clinical examination. In the second case it was indicated by the results of clinical examination. The pathologic condition of cirrhosis of the liver was present in both cases. In the first case atrophic cirrhosis of advanced degree was found at autopsy. In the second case the diagnosis of cirrhosis was based on the finding of an enlarged liver plus the marked alcoholic history of the patient.

16. **Serum Treatment of Exophthalmic Goiter.**—The serum in the treatment of the five cases reported by Waterman was derived from blood drawn from the jugular vein of a goat two weeks or more after the removal of the thyroid gland. It was invariably used subcutaneously. The first patient received the serum in 1 c.c. doses, about five times a week, for the first three months, and then 2 c.c. doses, about twice a week, for the next three months, after which time 3 c.c. were given every eight or ten days for two months. The patient has been free from any signs of the disease for a year and a half. The pulse varies between 70 and 75. The second patient was given daily doses of 2 c.c. of serum for a week, when a general urticaria developed necessitating the discontinuance of the treatment for two weeks. At the end of this time she was given daily doses of 1.5 c.c. for a period two weeks, and then 3 c.c. once a week for two months, and once a month for three months. Six months after the treatment was stopped there were no signs of the disease and the patient was well in every respect. The same treatment was given in the remaining three cases, but not with equally good results. Two of the patients were improved, while one remained unimproved. In one of the improved patients the treatment was continued for eight months, and it is interesting to note that the hair of this patient has become dry and brittle and is turning gray. In none of these cases was the disease of more than four years' duration. The two patients who were cured were of one year and four years' duration, respectively.

27 *Surgical Treatment of Prostatic Hypertrophy. S. P. Dela New Orleans.

27. **Treatment of Prostatic Hypertrophy.**—Delaup reviews the operative treatments for prostatic hypertrophy that have been found to be the best, and concludes as follows: A routine method is not applicable to the treatment of prostatic hypertrophy; every case is a law unto itself, and the treatment will depend on the various conditions presented in each individual case. The prostatic suffering from persistent severe cystitis, or difficulty or pain in catheterism, should early receive operative relief; delay is destructive to his urinary apparatus, and hence to his chance for life and comfort. The dangers attendant on the daily catheterism are greater than those of a radical operation performed at the onset of the symptoms caused by the obstruction, and the earlier the operation the fewer will be the complications encountered. The choice of operation must be determined partly by the patient's vigor and partly by the condition of the bladder and kidneys. In patients too weak to withstand an operation, suprapubic drainage is advised, and if improvement follows this procedure, then a radical operation is indicated. The proper time to perform a radical operation is reached as soon as it becomes necessary for a patient to resort to daily catheterism. A perineal prostatectomy is best suited for those patients in whom the enlargement of the lateral lobes has a tendency to progress toward the rectum, to obstruct the urethra; or to project backward into the bladder. This method is applicable in fully 90 per cent. of all cases, and is the surest, the safest and probably the quickest method of curing the patient. In early operations the results are most satisfactory, recovery rapid, the mortality varying between 5 and 7 per cent. Suprapubic prostatectomy, combined with perineal drainage, is wisest when there is an enormous intravesical hypertrophy of the lobes, especially if the condition is associated with tumor formation projecting well back into the bladder. A prostatectomy is usually attended with more risk than the Bottini operation, and the convalescence is more prolonged. Therefore, in suitable cases in which the general health and kidneys contraindicate more radical measures, and also in those cases in which prostatectomy is refused, the Bottini operation is especially indicated.

August.

28 *Nostrums and Proprietary Medicines. J. Hunter, Toronto.
29 Medical Thoughts, Facts, Fads and Fancies. J. S. Sprague, Stirling, Ontario.
30 Sir Charles Hastings, the Founder of the British Medical Association. J. Ferguson, Toronto.

28. **Nostrums and Proprietary Remedies.**—Hunter prescribes conditions as they exist and suggests remedial measures. He says that materia media, pharmacy and therapeutics, as compared with the other branches of medicine, are in a morbid state. Our knowledge of these is, he declares, lamentably defective, the literature is rankly unscientific, and our practice empirical and eratic. The first thing necessary in the way of a remedy is a radical change in the curricula of our medical colleges. The most competent teachers should be provided, and these should be enthusiasts. There is too much nihilism in therapeutics. Time and facilities for teaching these sub-

jects profitably and intelligently should be provided. The importance and value of a thorough knowledge of materia medica and therapeutics should be indellibly impressed on the mind of every medical student. Therapeutics should be taught not only rationally and practically, but in minute detail. The mere enumeration of principles is not sufficient. A suitable selection of drugs should be made and the properties of these thoroughly learned, in order that the student may know how to prescribe them so as to get their full medicinal effects. When physicians have learned the art of prescribing standard remedies in an attractive and palatable form the field of rational and scientific therapeutics will be reclaimed.

The individual physician should replenish his library with the best literature to be procured on these subjects. He should not be led astray, Hunter says, by mercenary or fraudulent literature into prescribing nostrums whose composition is unknown. Every physician should take the time necessary to become thoroughly acquainted with all the drugs and remedies he needs to use. Every physician should point out to his patients the evils arising from the indiscriminate use of any drug or remedy. Medical associations and societies should use every means at their command to mitigate these evils. Far more attention should be given to materia medica and therapeutics at medical meetings. Committees should be appointed to investigate all new remedies. Medical journals should positively refuse to advertise any preparation, drug or compound whose composition and qualities are unknown. No medical journal, manufacturer or exploiter has any right to imperil the lives of others for gain or any purpose whatever.

36 Hemorrhoids. C. J. Drueck, Chicago.
37 Treatment of Abortion and Miscarriage. M. Whise, Chicago.

34. Removal of Tonsils.—Stein believes that the best method of surgical treatment of the tonsils is the one that insures the possibility of the removal of all of the glands. He employs a procedure that combines the best features of two of the oldest and best known methods—namely, dissection and use of the tonsillotome. After the tonsil and the faucial pillars have been anesthetized, the gland is dissected free from its mucus and any fibrous attachment. The important feature of this part of the operation is that the gland must be deeply and firmly engaged in the tenaculum forceps in order to secure a very firm hold on the mass when traction is brought to bear. The traction is at first inward, toward the mouth, downard and backward. This is furthered by a backward rotation of the engaged forceps. The attachments are now all at extreme tension, and with a small sharp bistoury or small curved scissors incision is commenced well up in the epitonsillar fossa and carried down along the anterior edge of the palatoglossal muscle, hugging the capsule and avoiding the muscular fibers. Any posterior attachments are severed in the same manner, but by reversing the rotation of the engaged forceps to a forward position. Special effort should be directed to the liberation of the large mass of the gland found tucked away in the epitonsillar fossa. The fenestra of a Mackenzie pattern tonsillotome is now made to encircle the gland close to its posterior attachment, and while strong traction with the forceps is continued, the blade of the tonsillotome is driven forward, severing at one stroke the remaining portions. In place of the tonsillotome a special pair of curved scissors, or the cold or electric cautery wire loop, may be used with success.

39 Length of the Primary Incubation Stage of Syphilis. A. Post, Boston.
40 Arsenic in Pityriasis Rubra Pilaris. M. L. Heidinsfeld, Cincinnati.
41 *Case of Lupus Erythematosus in Early Childhood. J. F. Schamberg, Philadelphia.

38. Treatment of Epithelioma by Caustic Potash.—Van Harlingen records the results he has obtained in the treatment of 55 cases of epithelioma by the use of caustic potash. The ages of the patients ranged between 35 and 94 years. Thirty patients were males and 25 were females. Almost all tumors were located on the face. The left cheek was the seat of the lesion in 10 cases; the left side of the nose in 9 cases; the right side of the nose, the right cheek and the right temporal region, 4 cases of each; left cheek and left temporal region, 3 cases each; left lower eyelid, 3 cases; each ear, 1 case; each side of the upper lip, 1 case. Most of the lesions were quite small, the largest measuring 3 cm. in diameter. In almost all the cases entire reliance was placed on the caustic potash. Occasionally, slight relapses, or what appeared to be such, were treated with one of the mineral acids, formalin, etc. The wounds healed in from ten days to eight weeks, the average duration being four weeks. In the majority of cases so treated, the results were entirely satisfactory. In seven instances, the treatment was unsatisfactory or a complete failure, from several causes. Van Harlingen concludes that cases of epitheliomata of the skin that display small, well-defined pearly lesions, from one-half to 1 or even 2 cm. in diameter, found chiefly on the face and adjacent parts, are best treated by the use of caustic potash. Larger lesions are best treated by the *x*-ray, but here caustic potash may be used to soften and to dissolve the horny epithelium and in some cases as an adjuvant. In cases treated with caustic potash the use of the *x*-ray does not appear to hasten the process of reparation or to modify to any marked degree the cicatrix resulting from cauterization.

41. Lupus Erythematosus in Early Childhood.—The patient referred to by Schamberg was four years and three months old when the disease began. The first lesion appeared on the right cheek in the form of a pimple. This gradually increased in size, and later another lesion appeared on the left cheek. There is no dilatation of sebaceous glandular orifices. The case represents the vascular type of the disease.

42 *Collateral Circulation, Following Ligation of the Femoral Artery. F. Rustin, Omaha.
43 Neuralgia. F. E. Coulter, Omaha.
44 Intraocular Foreign Bodies. W. M. Cowgill, Lincoln.
45 Surgical Fever. J. M. McLeod, Lincoln.

42. Collateral Circulation Following Ligation of Femoral Artery.—Rustin reports a case of successful ligation of the femoral artery for popliteal aneurism and in which two years later he did a hip-joint amputation for a septic gonorrheal knee. The aneurism was of traumatic origin following a gunshot wound. Two silk ligatures were brought around the femoral artery, about two inches below the profunda and about one-half inch apart. The artery was not cut between the ligatures. For a few days after the operation there was some swelling and edema of the leg and foot; then the leg gradually became normal; the tumor diminished in size and there was every evidence of complete return of circulation below the ligature. As stated, a hip-joint amputation was done two years later. The amputated leg was preserved and the artery injected. The section showed that the main line of circulation was carried on through the anastomosis of the profunda artery, which was very much enlarged. The perforating arteries of the profunda were large and tortuous and anastomosed freely with the ascending branches of the popliteal artery. The external circumflex artery anastomosed freely with the superior articular branch of the popliteal artery. There were few anastomoses between the external circumflex branch of the profunda with the vessels in the gluteal region. Rustin says that at the time of operation he noticed that there were many small vessels, more than are usually encountered in the ordinary hip-joint amputation. The original aneurismal sac was obliterated, and its only remnant was a cord-like mass about four inches long and an eighth of an inch in diameter.

49 *Case of Extrauterine Gestation; Operation, a Living Child Delivered Weighing Three Pounds. H. T. Sutton Zanesville.
50 Points in the Hygiene and Sanitation of Rearing Children. D. S. Hanson, Cleveland.
51 Address of Welcome Delivered Before the Ohio State Medical Association at Canton, Ohio, May 9, 1906. J. F. Marchand, Canton.
52 Report of the President of the Ohio State Medical Association. T. C. Martin, Cleveland.
53 Cesarean Section—Twin Pregnancy, Multiple, Fibroids, Hysterectomy. J. F. Baldwin, Columbus.

46. **Stiff and Painful Shoulders.**—Under this title Codman considers cases of obscure lesions of the shoulder joint, often called rheumatism, fibrous ankylosis, paralysis of the deltoid, etc., the result of a blow, sudden muscular exertion, pressure, overuse or inaccustomed use. Codman believes that the trouble is due to subdeltoid adhesions and that the logical treatment is breaking up of these adhesions and then preventing their reformation by means of a splint which holds the arm in abduction and external rotation, thus bringing raw surfaces opposite healthy ones. The frame of the splint he uses is made of light iron wire, one-quarter of an inch in diameter and stiff enough to maintain its form and to carry the weight of the arm. Sufficient cotton wadding to thoroughly pad it is bandaged over it, and the whole is covered with cotton or a linen cloth. The splint should be long enough to extend from the axilla to the seat of the chair on which the patient sits. It is best held in position by a belt around the pelvis and a figure of 8 flannel bandage about the shoulder, crossing back of the neck. The pad should be placed on the opposite axilla to prevent excoriation of the skin by the bandage. The splint passes along the under surface of the arm, which is elevated in front of the body on a level with the head and slightly flexed, to the axilla, and then down the side of the chest over the hip to a point where it will just touch the seat of the chair on which the patient sits.

49. **Extrauterine Gestation.**—Sutton reports an unusual case of this kind. The patient was a primpara, 26 years of age. At three months uterine pains became so severe that the attending physician advised an attempt to empty the uterus, but he failed to deliver the fetus. At six months the same performance was gone through with by another physician, with the same result. At eight months she was taken very ill with pain over the abdomen, nausea, vomiting and great weakness. An extrauterine gestation was diagnosed and an operation advised. The abdominal incision brought into view a ruptured sac with a head presentation. A living child was delivered. A supravaginal hysterectomy was then done and the sac and uterus removed together. The patient died from shock thirty-six hours afterward. The child lived twelve hours. It was perfectly formed and weighed 3 pounds.

American Journal of Urology, New York.

August.

54 American Urological Association. F. C. Valentine, New York.
55 President's Inaugural Address to the New England Urological Society. O. C. Smith, Hartford, Conn.
56 *Sequelæ of Prostatectomy. R. F. O'Neil, Boston.
57 *Results of Prostatectomy. H. Cabot, Boston.
58 Indications, Contraindications and Management of Prostatectomy. C. G. Cumston, Boston.
59 *Sigmate Ureteral Obstruction. A. E. Gallant, New York.
60 Intravesical Operations with the Aid of the Cystoscope. H. Meyer, San Francisco.

56. **Sequelæ of Prostatectomy.**—O'Neil reviews 115 cases of perineal and 93 cases of suprapubic operation recorded by Proust. Of the perineal operations, 8 patients died, of the remaining 107, 55 cases had some postoperative condition, often several, orchitis occurring 14 times, fistulæ 14 times, of which 5 were temporary, residual urine 20 times. In 10 cases there was marked frequency of urination. In 30 other cases, only 8 of which are included in the 55 because of other conditions, a moderate amount of frequency of urination was present, that is, from two to four times at night and every three hours during the day. The beginning of micturition was given in 66 cases; longest 70 days after operation; shortest 5 days; average 26 days. Of the 93 suprapubic cases, 11 patients died. Of the remaining 82, 12 patients had sequelæ (this includes 2 cases of shock and 1 of hemorrhage), 4 suffered from frequency of urination, 2 from slight residual urine, 1 from abscess, 2 had orchitis, one of the latter cases proving fatl. Micturition began on an average 17 days after operation, the longest time being 45 days after operation, the shortest three days. By comparing the two series of cases, it is evident that the perineal route is much the more liable to troublesome sequelæ.

57. **Results of Prostatectomy.**—Cabot uses as a basis for his study the reports of surgeons of experience, who report not less than 14 cases, one year or more after operation. Of 495 patients operated on, 388, or 78 per cent., were cured. The percentage of cures was much greater in the cases of complete retention than in those of incomplete retention; 85 per cent. in the former, and 40 per cent. in the latter.

59. **Sigmate Ureteral Obstruction.**—Gallant cites the history of a patient suffering from an abdominal tumor, which apparently originated in the pelvis, but proved to be a hydronephrotic kidney induced by prolapse and the subsequent formation and agglutination of an s-shaped flexure of the ureter at its junction with the renal pelvis. Points of interest which came up during the course of the case were (a) the complete restoration of the ureteral caliber as soon as the inflammatory bands were removed; (b) the resumption of secretory function shortly after the kidney was replaced and the ureter freed; (c) the gradual recurrence of obstruction, with infection of the kidney and pelvis; (d) the excellent work of the remaining kidney after the affected kidney had been removed.

61 A Few Wounds Observed During the Japanese-Russian War. C. Lynch, U. S. Army.
62 *Some Operations of Unusual Interest on Women. A. Brothers, New York.
63 Cases of Hematuria. F. Cabot, New York.
64 African Recurrens. R. Koch, New York.

62. **Operations of Interest.**—The first case reported by Brothers is one of appendicectomy performed on a woman, pregnant three and a half months, without interrupting pregnancy. The appendix contained three fecal concretions. The second case was one of LeFort's operation for vaginal hernia following hysterectomy in a woman 60 years of age. The result was perfectly satisfactory. In the third case the uterus and vagina were removed *en masse* by vaginal hysterectomy for the cure of prolapsus uteri in a woman 50 years old. The patient recovered. The fourth case was one of perforation of the intestine by a fish bone. The patient, a woman, 60 years old, had apparently been cured two and a half years previously of tuberculous peritonitis by incision and drainage. A sinus leaking during the six months following left her with a ventral hernia. After considerable difficulty the intestines were separated from the anterior abdominal wall and from each other until a large cavity, containing about 8 ounces of a straw-colored liquid, was perforated with the finger. While separating adhesions an ulcer of the intestine presented and projecting from its center was a sharp point which proved to be a fish bone measuring nearly 1¼ inches in length. After depressing and inverting the ulcer its base was drawn together by means of a circular tobacco-pouch suture passed around the margin of the ulcer. To reinforce this suture a few extra Lembert sutures were passed in a second tier, completely burying the first suture. The hernia was treated in the usual manner.

71 Case of Hyperemesis Gravidarum. E. S. Bramlett, Oxford.

69. **Veratrum Virid in Eclampsia.**—Fletcher regards veratrum as much of a specific in eclampsia as is quinin in malaria. He administers the veratrum hypodermically in doses of from 15 to 65 minims, depending on the severity of the case. He has also used it with benefit in cases of infantile convulsions,

delirium tremens, pleurisy, pneumonia, sunstroke, gastralgia, enteralgia and other conditions accompanied by spasmodic pain.

70. Venesection in Puerperal Eclampsia.—Thornton advocates venesection, withdrawing at least a quart of blood by actual measurement. He does not think it necessary to inject saline solution because of the ever present edema.

August 4.

1 Development of the Treatment of Uterine Fibromyomata within the Last Twenty-five years. F. W. N. Haultain.
2 *Dysmenorrhea. A. Routh.
3 *Series of Fifty Consecutive Abdominal Sections. R. P. R. Lyle.
4 *Obstetric Experiences. J. Lindsay.
5 Evaporation of Chloroform During Inhalation. A. G. Levy.
6 Landry's Paralysis. E. MacNamara and J. Bernstein.
7 *Case of Abdominal Fissure. H. Stevenson.
8 Ascaris Lumbricoides as Cause of Appendicitis. A. Castellani.

2. Dysmenorrhea.—In the treatment of dysmenorrhea due to anemia, Routh has found the following an excellent prescription to be taken, after food, three times daily:

℞.	Liq. ammoniæ acetatis	ʒii	8	
	Ferri et ammoniæ citratis	gr. vii		5
	Tr. calumbæ	Mxxx	2	
	Liq. potass. arsenicalis	Miii		2
	Magnesii sulph. q. s.			
	Aquæ chloroformi ad	℥i	30	

M. Fiat haustus.

A week before the period is due, ten grains of bromid of potassium may be added to this combination, or salicylate of soda, if a rheumatic tendency is present. For the relief of pain Routh has found the following very serviceable:

℞.	Tinct. cardamomi co.	ʒss	2	
	Tinct. zingiberis fort	Mc		3
	Liq. ammoniæ acetatis	ʒiv	16	
	Antipyrini	gr. v		3
	Potassii bromid	gr. xv	1	
	Aquæ caryophylli ad	℥i	30	

M. Fiat haustus.

A dose of this is to be taken when the pain is present, and repeated, if need be, in two hours. If stronger sedatives are required, a cachet containing three grains each of antipyrin, phenacetin and citrate of caffein has been found to answer better than larger doses of the same drugs separately. If the extremities are cold, or if the patient feels chilly, prompt relief may be afforded by the inhalation of amyl nitrate (3 minims), or by taking nitroglycerin (grain 1/100). In congestive dysmenorrhea, where the antispasmodics fail, extract of cannabis indica (grain 1/3) or a combination of hydrastis, belladonna and bromid of potassium or sodium afford prompt relief. In cases of pelvic congestion with cold extremities and cold skin, Routh has found nitroglycerin to be remarkably effective. Ten grains of the compound powder of ipecac, combined with 30 grains of bromid of potassium, is often very useful if the patient is seen towards night time. Hot douches, local applications of iodin, glycerin tampons, gelatin pessaries, and assuming the genu-pectoral position for ten minutes at bedtime, are also useful means of emptying the pelvis of venous blood.

3. **Fifty Consecutive Abdominal Sections.**—Lyle reports 50 consecutive abdominal sections performed in an ordinary attic of a small (six beds) hospital, under the most restricted conditions and with the simplest technic. Every possible precaution was taken to avoid sepsis or shock. There was only one death.

The following operations were performed: Ovariotomy, 17; supravaginal hysterectomy, 8; salpingectomy, 5; salpingo-ovariectomy, 4; enucleation of broad ligament cyst, 4; celiotomy, 4; myomectomy, 3; ventrofixation, 3; panhysterectomy, 2. Six patients operated on for rupture ectopic gestation made uninterrupted recoveries. The one patient who died had a suppurating multilocular ovarian cyst with purulent peritonitis. Lyle concludes that his good results may be ascribed to a correct diagnosis, simplicity in technic, use of few instruments and appliances, limitation of size of abdominal incision, correct adjustment of all cut peritoneal surfaces, complete closure of the abdominal cavity without any drainage, and the free use of normal saline solution in cases in which purulent material is accidentally spilled in the pelvis or abdomen during the performance of an operation.

4. **Obstetric Experiences.**—Lindsay discusses his experiences with 5.845 cases of labor distributed over a period of 47 years. These cases occurred in his own practice, although about half of the number were in charge of his assistants. More than half of the deliveries were conducted with the patient on her knees, holding on by a chair, the woman refusing to go to bed. No use was made of antiseptics, except an antiseptic oil or grease for the finger, hand or instruments. The most careful asepsis was insisted on. There was no shaving of the parts, no washing, no syringing. Lindsay did all his work without uncovering the patient, except when using instruments or when anything unusual arose. During his first ten years of practice, when antiseptics had no place in the obstetric bag, he did not have a death. His first death was the result of puerperal fever, imported by a nurse. Among this total number of cases there were 2.309 forceps cases; 19 cases of version; 12 cases of placenta prævia; 13 cord presentations; 40 breech or feet presentations; 71 cases of twins; 3 cases of triplets; 52 occipito-posterior presentations; 13 face presentations; 2 cases of inversion of the uterus; 2 cases of hydatidiform mole; 8 monstrosities; 126 premature births; 3 cases of rupture of the uterus; and 5 cases of indentation of the frontal bone, due to forceps delivery.

There were 28 deaths in this series of cases, only one being the result of puerperal fever. Other causes of death were erysipelas, pneumonia, measles, phlebitis, peritonitis, convulsions and embolism. In the entire series there were only 6 cases of rupture of the perineum; none were complete.

7. **Fissure of Abdominal Wall.**—The subject of the report made by Stevenson was a seven to eight months' premature female child, first seen about two hours after birth. A large mass of bowel lay exposed outside of the abdomen without peritoneal or other covering. It consisted of all the large intestine and several inches of the small, with a patent Meckel's diverticulum about two inches in length. The fissure was between one and two inches in length. Stevenson removed the diverticulum flush with the bowel and closed the fissure. The child rallied well from the operation. The stitches were removed on the fifth day, when everything seemed well. On the sixth day the child became jaundiced and the evening of the eighth day it died.

14 Some of the Pseudo-Parasites of Cancer. A. S. Grunbaum
15 *Case of Acute Rheumatism; Hyperpyrexia; Recovery. E. B Smith.
16 *Treatment of Catarrhal and Gangrenous Dysentery. C. B S Amos.

11. **Addison's Disease.**—Short summarizes his paper as follows: 1. The symptoms of Addison's disease are due to vasomotor paralysis. This is due to absence of adrenalin, the normal excitant of the sympathetic nerve endings, from the blood. 2. The pigmentation is due to vascular relaxation of the skin causing exaggerated functional activity of the pigment cells. 3. The most promising line of treatment, on theoretical grounds, is the administration of vasoconstrictors of prolonged action; digitalin has given good results in one case.

15. **Hyperpyrexia in Rheumatism.**—The highest temperature, by rectum, in the case reported by Smith was 109.3; highest mouth temperature, 107.2. Cold baths were employed to reduce the temperature, and to these is ascribed the recovery of the patient.

16. **Treatment of Dysentery.**—Amos has had very satisfactory results in the treatment of dysentery from the employment of Manson's method of administering ipecac, associated with the following diet: All his patients are Africans, Asiatics, or Turks, and nearly all of them evince a very great repugnance to milk diet, frequently starving themselves for days rather than take it. Moreover, unless the milk is greatly diluted, hard curds constantly appear in the patients' stools. He has therefore abandoned a fluid diet in all cases of dysentery and has had recourse to a drier diet which the patients relish and take readily, even when in a most serious condition. They receive half a pint of milk at 7 a. m., when those without hemorrhage also have a small piece of bread; at 11 a. m. a plate of finely mashed rice, potatoes, lentils, macaroni, or beans, over which a little meat soup has been poured, is served. Convalescents also have a small piece of bread. At 5:30 p. m. they have a similar meal. During the night they have a pint of milk diluted with water to the patient's liking. Those who are very weak have in addition each day the whites of four eggs beaten up with brandy or water. The yelks of eggs they can not digest. No pure water is given, but a 1 in 3,000 solution of lactic acid is placed at the bedside for them to sip at will. With this dietary blackened tongues become moist and clean in one or two days, thirst disappears, no undigested food appears in the stools, and no difficulty is found in inducing the patients to take nourishment.

19. **Practical Points About Vaccine Lymph.**—Enterican describes an apparatus by means of which it is possible to fill hundreds of capillary tubes with vaccine lymph at one time with a great saving of lymph. The apparatus has been in use for over a year and has stood the test of time and experience.

20. **Value of Revaccination.**—This subject has been made one of careful study by Macgregor, and as a result of his work he draws the following conclusions: In adults not previously revaccinated the greater number are successful on revaccination, though this majority is not large. One previous revaccination, whether successful or not, renders the chances equal of a second revaccination succeeding or otherwise. In case of two previous revaccinations, successful or otherwise, success at a third revaccination is improbable. The period of life at which revaccination is more likely to succeed is before the age of 25 years. Those with good scars are much more likely to take on revaccination than those with poor scars.

32. **Foreign Body in Orbit.**—Pockley reports rather a curious case. A boy, while playing at school, was knocked against a wooden fence and immediately afterward pulled a splinter of hard wood out of his right eye. As soon as he recovered from the concussion he discovered that he had no perception of light in that eye and that the ball was protruded somewhat. There was tenderness on pressure in the orbit below the eye, but not elsewhere. An incision was made through the conjunctiva, midway between the inferior oblique and inferior rectus, and a hard wood splinter three-quarters of an inch long was withdrawn. Careful probing revealed no other foreign body. The disc of that eye eventually passed into a condition of white atrophy, the eye being normal in position and range of movement. There was no pain or tenderness. Four years afterward, on awakening in the morning, the boy found sticking out of the corner of his eye a piece of wood one and on-equarter inches in length, and one-eighth inch in thickness. There had been no pain or swelling previously and nothing had been noticed when the boy went to bed the night before.

37. **Sanitary Conditions in Japanese Army.**—This official communication from the medical inspector general of the Japanese armies describes the principles followed and the results obtained in the effort to keep the soldiers in good health. It concludes with the proud statement: "If it can be said that the Russo-Japanese war has no precedent in history in modern times in regard to its extent and its importance, it may be said with equal truth that our sanitary institutions won an equally unique victory." The mortality from disease was only a third of that from wounds. Beriberi was the cause of 25 per cent. of all the admissions from disease to the hospitals. The percentage of wounded was about 14.58 per cent. of the total active force. Smallpox, typhoid fever and dysentery reign in Manchuria nearly all the year, and as the soldiers were quartered by preference in the Chinese houses, the danger of infection was great. To attenuate this danger physicians were sent in advance of the troops and every available house and family were examined in order to recognize the contaminated and to exclude such houses from the occupancy of the troops, while the sick persons encountered were given careful treatment. A portable apparatus for steam sterilization of clothing and blankets was extensively used, and with excellent results. No injections of serum for typhoid fever dysentery, cholera or plague were made, as their effects are not always constant and with such an extensive battle line it would have been impossible always to wait for the febrile reaction. Each hospital ship had its own steam sterilizing plant, and each hospital train was carefully cleaned and disinfected each time after unloading.

38. **False Mitral Stenosis.**—Bard reviews the points useful for the differentiation of true from false mitral stenosis. The latter should be suggested by the occurrence of the signs in young chlorotic girls or nervous individuals. On the other hand, the presence of infantilism or tardy development should suggest the possibility of organic defect. An important differentiating point is what he calls the "vibration clôturale," that is, the changes in the audible vibration as the valve closes, the normal vibration being modified by the rigidity and induration of the valve in case of organic defect. This "clotural vibration" is plainer to the palpating hand than the modifications in the sounds to the ear. It is not affected materially by arrhythmia or tachycardia, which are liable to arrest the *thrill*. The exaggeration of mitral vibration from mere hyperfunction, without organic changes, is revealed by a wide, diffuse vibration without any localizable maximum, while it is scarcely attenuated by the interposed hands, and is exactly proportional to the extensive shaking of the wall over the heart. With organic changes there is more localized vibration; it has a deeper, more acute character, with little if any shaking of the wall. There can be no confusion between these two types except in case of pronounced palpitations and exaggerated *functioning masking the character of the vibration*. By waiting for a period of calm, the characteristics of the hard vibration may be detected. In false mitral stenosis the thrill is discerned, but the hard "clotural vibration" is absent, and this absence renders the significance of the thrill somewhat dubious. Differentiation is possible only by careful study of all the usual signs, but the special characteristics of the audible mitral vibration are of especial importance in this respect.

40. **Renal Origin of Permanent Arterial Hypertension.**—Ambard reviews the various types of arterial hypertension and the mechanism of its production. He is convinced that an exclusively mechanical hampering of the kidney secretion is the cause of the various types of exaggerated arterial tension encountered in the course of nephritis. When this mechanical hampering is variable, the arterial tension varies with it, and when it is invariable the hypertension is invariable. The variable effects of the retention of salt in the different types of nephritis are like an experimental demonstration of the part played by the kidney in the production of arterial hypertension. The fact that primary arterial hypertension seems to exist in certain cases is due to the presence of an unsuspected nephritis not accompanied by albuminuria, revealing its presence only by this mechanical interference with the kidney secreting function. It may be compensated by the increased arterial tension so perfectly that the existence of the nephritis is rendered dubious. Careful investigation of the permeability of the kidneys and autopsy of individuals of this category, dying accidentally, reveal the latent nephritis. In conclusion he remarks that the more one examines in detail these cases of permanent hypertension, the more convincing are the findings to the effect that there can be no permanent arterial hypertension without nephritis.

49 Physical Laws and Influence of Mineral Waters on Stomach Functions.—Können wir den Einfluss der Mineralwässer auf die Magenfunktion auf Grund physikalischer Gesetze erklären? B. Tausz.

42. **Pyuria Without Suppurative Processes.**—Talma describes 2 cases in which pus cells were found in the blood and urine

without a suppurative process being discovered anywhere in the body at autopsy. Large numbers of polynuclear leucocytes were found in the urine, and pus was discovered in small amounts in nearly all the organs, but without any local suppuration anywhere. The kidneys were perfectly sound in appearance. The pyuria was induced solely by leucocytosis in both cases reported, favored possibly by exaggerated permeability of the vessel walls. The patients were men 34 and 59 years old. The second patient had a small contracted kidney and chronic tuberculous lung lesions, but no suppurating process.

43. **Precipitins of Cow's Milk Found in Infant's Blood.**—Bauer was able to detect by the biologic hemolytic test the presence of cow milk precipitin in the blood of an infant suffering from severe atrophy. The toxic action of a foreign albumin has long been established, and this may have been the cause of the severe atrophy. The test was made with progressively smaller amounts of the human serum, plus 0.03 c.c. of the precipitating rabbit serum, plus 0.4 c.c. of fresh goat serum, the whole kept at 37 C. for an hour and a half. Then 1 c.c. of a 5 per cent. suspension of sensitized corpuscles from goat blood was added.

44. **Definition of Hysteria.**—Kronthal argues that hysteria can not be regarded as a nervous affection. It is the varying morbid reaction of the cells constituting the individual. Treatment should aim to influence the morbidly reacting cells by changing the environment and by strengthening the cells —the benefit from which has long been established empirically.

45. **Lupus of the Mucosa of Upper Air Passages.**—Senator has had occasion to observe 35 cases of lupus of the face in which the affection involved the mucosa of the upper air passages. In 22 the affection had commenced before the age of 25. Treatment of these comparatively inaccessible regions is by curetting into sound tissue, and examining the patient every three or four weeks to remove any foci overlooked or recurring. A 50 per cent. solution of lactic acid may be found useful when for any reason it is impossible to use the curette. Treatment with direct sunshine might be advisable for laryngeal lupus according to Sorgo's successful technic.

46. **Functional Treatment of Fractures.**—Deutschländer rejects immobilization and sparing the limb after a fracture as an irrational and harmful method of treatment. On the contrary, he preaches that the natural healing processes are promoted and hastened by functional use of, the limb from the start. Massage is a subordinate aid. The functional use of the limb, however, must be guided, as not all movements are beneficial. Those only must be allowed which correspond to the pathologic conditions and the mechanism of the parts. The novice in this method should commence with treatment of fractures of the finger phalanges. The functional technic is particularly effectual in case of fractures of joints. The results in 73 workingmen with fractures of the arms, treated by this functional technic, were that the fracture healed in 67 without impairing in the least the working capacity. The working capacity was impaired permanently about 50 per cent. in 2; about 40 per cent. in 2, and 10 per cent. in 2. Nearly 30 of these patients were over 40. He uses adjustable and removable immobilizing appliances, but always with a view to the functional use of the parts. The Bardenheuer extension treatment is a kind of functional therapy. He follows Hoffa's directions in regard to massage which must not be left to lay hands in case of fractures. The exercises of the limb must be slow and systematic and adapted to the individual conditions, usually with slight traction on the fractured limb. The movements may describe quite wide excursions, but they must not be abrupt nor excessive, and must never injure the new tissues forming in the process of repair. Both during the massage and the exercises the fragments must be fixed in the position in which healing is desired, with at the same time slight correcting pressure on them.

47. **Treatment of Chlorosis.**—Bach found gastric hypoacidity is only a small proportion of 224 cases of primary chlorosis. The acidity declined under treatment with iron. He gives the tabulated findings in 11 cases under iron treatment.

48. **Uric Acid Diathesis.**—Grimm ascribes the deposits of urates to the peculiarly low standard temperature of individuals exhibiting signs of the uric acid diathesis. Some of his patients have permanently a temperature in the axilla of 35.8 C. The low temperature of the blood prevents the proper dissolving of the uric acid in the blood, and urates are deposited at the points where the temperature is constantly lowest, that is in the ears, hands, feet and joints. This assumption suggests an explanation for the rarity of gout in tropical regions. The metabolism is sluggish, and on account of this sluggish metabolism the uric acid is precipitated at various points in the body. Treatment should aim to stimulate metabolism, and he has found the Sauerbrunn mineral waters remarkably effectual in such cases. He has tested the dissolving action of these waters a hundred times by placing a number of small kidney stones in urine from a uric acid patient. He weighed the stones before and after leaving them in the urine for a day or two. The patient then ingested a quart or three pints of the Sauerbrunn waters daily and the test with the kidney stones was repeated. They were found to lose constantly in weight in the urine voided under the influence of the mineral water. Five small stones in one instance, weighing 45 mg., weighed only 28 mg. after three days in the urine, rendered strongly alkaline by drinking the Sauerbrunn waters. One of the stones crumbled to pieces. In treating the acute attack, warmth only should be allowed. With the Sauerbrunn waters, hydrotherapy, exercise and superheated air, he claims that even the oldest cases of uric acid diathesis can be improved and in many instances cured.

51. **Origin of Pulmonary Tuberculosis.**—Schlossmann and Engel make out a strong case in support of the assumption that tubercle bacilli ingested are taken up into the system by the same route as particles of food. The mesenteric glands are used to the passage through them of corpuscular elements, droplets of fat, etc., and their behavior during digestion indicates that they differ functionally from the other lymph glands in the body. The bacilli entering the mesenteric glands are passed along to the thoracic duct, and from here they can readily infect the lungs and bronchi. Ingested bacilli are able to pass through the intact intestinal wall, through the glands and into the thoracic duct as readily and as rapidly as the food particles follow the same route. The authors found the tubercle bacilli in the lungs in young guinea-pigs a few hours after the bacilli had been administered in milk. Tuberculosis should be regarded as a "children's disease," in so far as its inception almost invariably occurs during childhood, although its manifestations frequently do not appear until later. Contracted pelvis causes no disturbances until the child-bearing age, and yet it is the result of a rachitic process in youth. The practical conclusions of the article are urgent appeals for the prevention and cure of tuberculosis in childhood. By strengthening the child's organism it becomes able to conquer the existing disease and develop an effectual immunity.

55. **Treatment of Wryneck.**—Doering describes the operative measures that have been successfully followed in 35 cases of congenital torticollis. Simple open tenotomy is the standard technic and the results are even better than with more complicated procedures. In 32 of the cases, including a number of severe ones, the cure was complete and permanent.

57. **Gonosan and Treatment of Gonorrhea.**—Schindler and Siebert comment on the extensively advertised drugs for internal treatment of gonorrhea, referring especially to gonosan. They assert that such drugs are dangerous, as they have a tendency to supplant the essential and indispensable local treatment. If it were not for this, they remark, "the manufacturing chemists and the charlatans—whose ranks include many apothecaries, unfortunately—might be left in peace to profit by the sale of this convenient and consequently popular method of treating gonorrhea." "But," they add, "internal treatment of gonorrhea is not effectual. Extensive tests and experiments at Neisser's clinic have demonstrated the absolute worthlessness of any treatment not strictly antibacterial, especially internal treatment. Gonosan has been subjected lately to special tests which have established that its internal administration does not affect the gonococci in any way and hence has no influence on the course of the disease." After taking 10 capsules of gonosan a day for three days they mixed 1 c.c. of the urine on the third day with a suspension of gonococci. Even under these extremely favorable conditions the gonosan urine did not have the slightest inhibiting effect on the growth of the gonococci in the test tube. Local tests of the gonosan showed that it was far less bactericidal than the silver salts, oxycyanid of mercury or ichthyol. They query therefore, why, if gonosan has no favorable influence whatever on gonorrhea, either internally or externally, that is, does not kill the gonococci or inhibit their growth, why has it happened that, notwithstanding this, gonosan has met with such a cordial reception on the part of many physicians? They ascribe this, first, to the fact that it is much more convenient to prescribe capsules internally than to apply effectual local treatment, and secondly, to the fact that many physicians still cling to the delusion that if the symptoms, the pain, smarting and discharge can be banished in the early stages, the disease is cured. And yet countless experiences have shown that the gonococci still lurk in the parts. It is the practice at Neisser's clinic to refrain from arresting the discharge at once, as otherwise the patient thinks he is cured and grows careless. Neisser prefers freshly prepared solutions of a silver salt for the local treatment, commenced at the earliest possible moment. If this does not always accomplish the desired result the trouble is generally in the inadequate technic on the part of the patients, and, unfortunately, on the part of some physicians. Everything claimed for the action of gonosan is uncertain and inconstant, while good results are invariably obtained by an early, energetic course of local treatment.

61. **Congestive Hyperemia from Standpoint of Endotoxin Theory.**—The results of experimental research harmonize with the clinical phenomena observed and emphasize the fact that the proper indications for the application of Bier's congestive hyperemia are the same as for the bactericidal serums. Wolff-Eisner reviews them in detail. The congestive hyperemia has the advantage over the serums that the evacuation of the endotoxins can be easily secured by incision. This evacuation is indispensable, and it is a mistake to suppose that the congestive hyperemia takes the place of surgical measures except in the very mildest cases. Lexer has shown that the congestive hyperemia causes destruction of some of the bacteria and consequent liberation of endotoxins, but the bacteriolysis is not complete, and some bacilli are proliferating while others are being destroyed. Unless an ample outlet is maintained for the escape of the endotoxins, the measure does more harm than good. But if free escape is provided, then the conditions are remarkably favorable for rapid healing. Wolff-Eisner remarks in addition to the above, that bacteriology and immunization and their problems should not be left exclusively to the theorizers, but should be taken into the clinic. They will there yield valuable fruits and the clinic in turn will render them of greater use. Modern clinical institutes should be equipped for such work with medical men trained in it and able to interpret the phenomena observed. This would prevent the blind and wasteful use of expensive serums on patients without the proper indications. The endotoxin theory is destined, he thinks, to play a most important part not only in the study of the origin of the disease, but also in its prevention and cure.

63. **Measurement of the Blood Pressure.**—Schilling expatiates on the great difference in the results observed when the constricting band is wide. He advises the use of a band 12 cm. wide, which gives much more accurate findings. The normal range is found to be less extensive than when a narrow band is used. With the Riva-Rocci and the 12 cm. band the blood pressure of the healthy adult ranged only from 110 to 125 mm. The average in 100 men was 118.1 mm. In 1,000 tests on 350 persons he found that instrumental measurement alone is reliable. Notwithstanding his wide experience, in estimating the blood pressure without the instrument, he frequently found that his impressions were far from the truth when the results were compared with those registered by the instrument. In many cases the blood pressure findings were the only clue to effectual treatment. He has sometimes derived great benefit from digitalis in cases with high pressure, the general health improving as the blood pressure dropped. As a rule, however, it is only a symptom and does not need to be treated separately. Krehl has recently pointed out that it may be merely a means of defense on the part of the organism in some cases.

64. **Treatment of Hypertrophy of the Prostate.**—Rörig has performed the Bottini operation in 203 cases, and has had only one mishap and one death in this series. The one patient who died succumbed to the results of uremic intoxication a few weeks after the operation. Rörig is an earnest advocate of the Bottini operation, believing that it should be the standard and that resection or excision of the prostate should be reserved for exceptional cases. His results are a complete cure in 47 out of 51 cases of chronic, absolute retention, that is, in 92 per cent., with 1 patient improved. In 132 cases of chronic, relative retention of urine, acute, intermittent retention, tenesmus and difficulty in catheterizing, 83 patients, 62 per cent., were completely cured, while 34 per cent. were much improved, and no result was obtained in 3, that is, in 2.27 per cent. In 20 cases of slight hypertrophy, 9 patients were improved and no effect could be discovered in the 11 others. He has never had recurrence in any of his cases. He always operates with the patient standing erect. He inflates the cleansed bladder with air, introduces the apparatus, hooks it in and allows the air to escape. When the patient states that he feels a desire to urinate, the knife is sprung back into its sheath, under 50 amperes, and air is injected again, after which the operation is continued. He then instills 10 c.c. of a 1 per cent. silver nitrate solution and has the patient lie down. In case of much congestion he leaves a catheter in the bladder. The prostate presents in such a way with the patient standing that a single cut is sometimes sufficient. He never operates under general anesthesia, as the bladder walls are liable to relax and the prostate to alter its shape. He ascribes to the chloroform anesthesia most of his failures, as in these he happened to operate under general anesthesia. A second operation later without chloroform soon rendered the cure complete.

65. **Evil Effect of Pregnancy on Laryngeal Tuberculosis.**—Levinger's opinion as to the injury from a pregnancy in case of laryngeal tuberculosis has been amply confirmed by his experience in 3 cases. In the first the woman died from the rapid progress of the laryngeal affection about two weeks after she had been delivered of an apparently healthy child. With the exception of hoarseness for two years (no laryngologic examination), there had been no indications of a throat trouble until after delivery, when an attack of suffocation and fever led to the discovery of the tuberculous tumor in the throat and lesions in the lungs. The patient did not survive excision more than a week or so, succumbing to hemoptysis. In a second case Levinger delivered the patient at the end of the fifth month on account of aggravation of a throat and pulmonary tuberculous affection as the pregnancy progressed. The patient bore the operation well, as also excision of the tuberculous tumor in the throat, and has since been in comparatively good health. In a third patient the deleterious influence of the pregnancy was likewise unmistakable.

66. **Permanent Paralysis After Spinal Anesthesia.**—König's patient was a man of 35, who fell, while drunk, and fractured the patella. A week later the patella was sutured under stovain spinal anesthesia, about 0.06 gm. stovain being mixed with the patient's own cerebrospinal fluid, which was then reinjected between the third and fourth lumbar vertebræ. In less than fifteen minutes there was complete anesthesia to the umbilicus, but none of the functions of the parts below the umbilicus returned; bladder, rectum and legs were entirely paralyzed, the motor and sensory functions, and the tendon and cutaneous reflexes were alike abolished. The entire region below the seventh dorsal vertebra was as dead as after a total lesion of the spinal cord, and after the usual sequence of cystitis and decubitus, death occurred in a little more than three months. Headache, nausea and fever had also been observed. The paralysis was complete from the very first, which speaks against an infectious origin. Autopsy showed the spinal cord adherent to the dura below the ninth vertebra, with signs of softening in the lumbar region and to a less extent in the thoracic, with a purulent fluid escaping on transverse section.

68. **Polycythemia.**—Köster remarks that nearly all the cases of polycythemia known were in middle-aged persons, the youngest was 20 and the oldest 60. He reviews the various cases that have been published and one from his own experience. The etiology seems to be still as obscure as ever, although it is apparent that the cause can not be a single one. The only point firmly established to date is the change in the blood-forming organs, but whether this is primary or secondary is still a mystery. See editorial in The Journal, Aug. 18, 1906, p. 510.

69. **Fracture of the Olecranon.**—The proportion of fractures of the elbow was 103 to 8,650 fractures of all kinds in von Bruns' experience up to 1903. Lendorf has encountered 21 cases in a total of 3,756 fractures. He describes and illustrates the various types, and says that treatment depends on whether the accessory extension apparatus is injured or not. If it is, operative measures are indispensable, and they are not indicated unless this is the case. The state of the accessory stretching apparatus is the key to treatment, and it must be determined as early as possible. When the point of the olecranon is involved in the fracture, and the anamnesis suggests that there was great strain on the muscles, the rupture is generally transverse and extensive. With the usual direct fracture, the diastasis is very large, while it is small if the tendons still hold. The more the upper fragments are fastened in a flexed position, so that they can not slip around from side to side, the greater the probability that the rupture is small. As soon as the local pain has somewhat subsided, sometimes the same day, but usually not for a few days after the accident, the condition of the stretching apparatus can be tested by having the patient extend his arm. This can be done without fear of rupture as the tendon fibers are too strong to tear with this exercise. The arm should be held so that the movements can be done in the horizontal plane. When the arm is extended it can also be ascertained whether or not the patient is able to hold it in the position which allows a weight on the forearm to cause it to bend. This same test is extremely useful in examining a fractured patella. One of his patients with the stumps fully 1 cm. apart was able—a few hours after the accident—to raise his leg while extended. This showed that the accessory stretching apparatus was almost intact—an important guide to treatment and prognosis. This exercise must be done very cautiously, and if it is excessively painful it is best to postpone it, although the results of treatment are better, the earlier it is undertaken. It is not enough to suture the bone, the ruptured tendons must also be sutured. The arm must be immobilized in a flexed position. If operative measures are not required, massage and movements are indispensable. Tilanus massages in all cases, beginning at once after the accident with daily séances, applying a flannel bandage to promote reabsorption of the extravasated blood in and around the joint, and fastening the arm in a splint holding it in extension. Passive bending and stretching of the arm follow and the bandages are discarded after three weeks, when the patient is allowed to use his arm. It is important not to allow active movements before this date. Flexion is more dangerous in all cases as the patient exposes the tendons to injury when he feels pain and strains the triceps. The arm must be held stretched during these first séances.

70. **Paralysis During Croupous Pneumonia.**—In Vogelius' 2 cases hemiplegia with aphasia developed three days after the crisis of croupous pneumonia in one case, and two days after the onset in the other. Both patients were young men and the paralysis proved permanent. One patient died a few months later of purulent meningitis and pericarditis. The few cases of pneumonic paralysis on record are reviewed and compared. Vogelius' patients were free from syphilis, alcoholism and arteriosclerosis, and had shown no cardiac symptoms. The meningitis was probably a pneumococcus metastasis. The patches of necrosis found in the brain in the case that came to autopsy explain the hemiplegia observed. The same can be said of the muscular atrophy and other changes in the legs in the other patients. Death is the rule in older persons; in the young the paralysis may persist for a long time, but in all the cases previously published complete recovery followed at last. The 2 cases now reported are peculiar on this account as one terminated fatally and there has been little improvement in the paralysis in the other to date. In the 5 fatal cases on record of tardy paralysis after pneumonia, meningomyelitis was found in 2, while there were no signs of it in the others. The trouble is probably the result of the direct action of the pneumococcus toxin on the nervous system, similar to the paralysis after diphtheria.

72. **Catgut That Can Be Boiled.**—Heerfordt has been trying for years to produce a catgut than can be boiled, like the instruments, just before using. He announced in 1904 that preliminary treatment with formaldehyd rendered the catgut able to resist the action of boiling water. At the same time, however, he stated that there was no certainty as to the sterilization of catgut thus treated, as it lost too much in strength if the process was pushed far enough to ensure sterility. He now

announces that this difficulty can be overcome by using catgut previously sterilized with dry heat or with Claudius' technic of leaving the raw catgut for 8 days in a solution of equal parts iodin and potassium iodid in 100 parts water, or if the catgut is sterilized by leaving for fourteen days in a 2 per cent. solution of carbolic acid, twice changed. The catgut thus sterilized is loosely wound on a frame and left for 24 hours in an aqueous 4 per cent. solution of formaldehyd. The frame with the catgut is then rinsed for a few moments in running water, and then placed for a few hours in a 2 per cent. aqueous solution of ammonia. The catgut is then wound into coils, rinsed in running water for about 24 hours, then placed in the ammonia solution for 8 hours, and rinsed in running water for about 12 hours. It is then carefully dried and wound in coils or on spools, ready to use. It resembles raw catgut in appearance at this stage. Just before using, it is placed in boiling water for from 10 to 20 minutes. The "koge-catgut" (catgut that can be boiled), prepared in this way, has only a very slight irritating action on the tissues, and sometimes none at all. In 12 tests the catgut was introduced into the cornea or into the anterior chamber of rabbits' eyes, and the symptoms of irritation were minimal. In 10 cases there was an insignificant pericorneal congestion, and in the others no symptoms developed indicating any irritation. The catgut was completely absorbed by the end of 2 weeks in every instance. One precaution must always be observed, namely, that the catgut must be taut when it is placed in the boiling water. He has devised a special suture holder for the purpose, which stretches the catgut and prevents its snarling, neither the needle nor the catgut coming in contact with the fingers. When the catgut is lifted out of the boiling water and left exposed to the air for a few moments, the partially dry surface offers an especially favorable consistency for suturing. Catgut thus prepared is in constant use in the ophthalmic clinic at Copenhagen and in Rovsing's hospital and private practice. It is regarded as an important progress both for the hospital surgeon and the general practitioner. Even the finest catgut (00 and 000) can be threaded dry in a very fine needle, and after both needle and catgut have been boiled, can be used in suturing nerves or blood vessels or in operations on the eyes. Before placing the catgut in the formaldehyd solution mentioned above, if it was sterilized with carbolic acid or with the iodo-iodid solution, these chemicals must be thoroughly removed by soaking the catgut in a 2 per cent. aqueous solution of ammonia for 2 hours and then rinsing thoroughly in running water. Catgut sterilized with dry heat is prepared by soaking for an hour in boiled water. After these preliminaries the sterilized catgut is ready for the formaldehyd mentioned above. Heerfordt would like to have sterile catgut prepared for surgical purposes under state guarantee. He thinks that the importance of the subject and the enormous demand justify something of the kind. It is rarely possible for tests of the sterilization of catgut to be absolutely decisive under present conditions. The real touchstone, that is, the most resistant germs—are seldom procurable.

76. **Tuberculosis of Adnexa Diagnosed with Tuberculin.**—Kemp's patient was a housemaid of 24, scrofulous as a child, but otherwise healthy until abdominal and slight pulmonary symptoms developed, varying in intensity during 3 years, with suppression of the menses for one year, with their reappearance later. Pains in the iliac region, especially on the left side, were frequent, and the girl became much emaciated. The tuberculin test was positive and tuberculous lesions were found in the tubes and one ovary, which were removed, leaving the other ovary. The patient rapidly recovered and no further symptoms have been observed, either from the lungs or abdomen. The case was rendered specially interesting by the lack of any local reaction in the lungs after the injection of tuberculin. This indicated that the lung process had healed, and encouraged operative treatment of the gynecologic tuberculous process. With the exception of the tuberculin reaction, none of the symptoms were pathognomonic of a tuberculous affection. He remarks that the tuberculin test has been applied in gynecology only ten times to date, according to the literature. Bossi, Meyer and Birnbaum used it in 10 cases, with a positive response in 6. Absolutely negative findings indicate the non-tuberculous character of the lesions, or, at least, that they do not require active operative intervention. A positive response without any local reaction also speaks against a gynecologic tuberculous affection.

77. **Huntington's Chorea.**—Wimmer's patient was a 1-para of 47 whose father, twin sister and 2 brothers presented the same syndrome. She had never had acute febrile rheumatism and also denied syphilis. Another patient was a physician 51 years old, who had suffered several times from recurring acute articular rheumatism during the last 10 or 12 years. His father had succumbed to paralytic dementia. Hallucinations in sight and hearing developed three years before the choreic movements were noticed, with obsessions of persecution and depression, and a rapid decline. The pathologic anatomy in this case is described in detail.

78. **Gastric Ulcer.**—Rubow reports 12 cases in all of which hypersecretion of gastric juice coincided with an ulcer. In 3 cases the diagnosis of ulcer was confirmed by an operation, in 4 others by the prompt success of treatment directed against the assumed ulcer, and in the others the history of the case rendered certain an ulcer with stenosis and cancerous degeneration. All these cases confirmed the intimate connection between an ulcer and the gastrosuccorrhea. The latter can be accepted, therefore, as an almost certain sign of ulcer. The finding of 50 c.c. of fluid or more in the fasting stomach in the morning, especially if very acid, is presumptive evidence of an ulcer. It decided the question in several dubious cases in his experience, especially in some in which obstinate constipation or other intestinal affection might have been responsible for the gastric symptoms. An ulcer in cancerous degeneration is liable likely to be accompanied by gastrosuccorrhea if the mucosa is still functionally capable. Madsen has reported 2 cases of cancer of the stomach accompanied by hypersecretion of gastric juice. How frequently it accompanies ulcer is not known, but it is more likely to be observed with the more chronic ulcers rather than in the new-forming ones. Its differential importance may be great, especially in cases in which the diagnosis wavers between ulcer, chronic intestinal trouble and a gallstone affection. In examining for gastrosuccorrhea it must be established that the patient did not drink during the night, and also that the tip of the sound is actually in the lowest part of the stomach, which in case of gastroptosis may be very low.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Address

THE OPPORTUNITY OF THE PEDIATRICIAN.*

THOMAS MORGAN ROTCH, M.D.
Professor of Pediatrics, Harvard University.
CAMBRIDGE, MASS.

THEN AND NOW.

In the year 1880, in the city of Richmond, in a small room containing a mere handful of physicians, I had the honor, as secretary of this Section on Diseases of Children, to sit face to face with the first members who inaugurated a great advance in medical investigation.

Your leader then who, although over a quarter of a century has passed by, still represents preëminently the broad principles of pediatric science, was chairman of this Section and established it on a firm basis. We were thus honored in the very beginning of our existence by having as our presiding officer the father of pediatrics in America—Abraham Jacobi. The name has proved of good omen, and the meeting of 1880 was an epoch in the history of the American Medical Association.

To-day I have been bidden, and have accepted the privilege with pleasure, to welcome in Boston the fully-developed Section on Diseases of Children of the present day; a Section which is no longer a handful of pioneers, of explorers in an almost unknown field, but which is large in numbers, assured by success, representing all parts of our great country; a Section no longer striving even for recognition, but constituting one of the strong, vital principles of the whole Association, and working on a ground which has been well broken and which has brought forth a harvest of original American ideas.

I welcome you to this eastern city which is so distant from your homes that we can but deem it a compliment that you have journeyed so far. I congratulate you on the progress which, through your efforts, has been made in your chosen branch of medical science, a branch as important as it is intensely interesting.

IMPORTANCE OF PEDIATRICS.

What more important, what more worthy work for the adult brain can there be than by the study of the early periods of life to aid in securing better conditions, physical and mental, in the infant, the child and the adult, and thus to strive to make the people of the future in our great republic worthy of, and fitted to deal with, the responsibilities which such a republic brings with it?

In your hands and brains rests the duty and power to make or to mar the citizens of the future, and to see that in this respect one decade is superior to the previous one.

What this Section was needed for, what it was formed for, what it was from the first intended to do, was to place the study of pediatrics on the same elevated plane that had been established for adult life. To accomplish this it had in the early years of its existence to be iconoclastic. This iconoclasm and patient originality have been the weapons with which those who have devoted their thought to the study of early life have fought their way to the front, and placed the standard of pediatrics where it ought to be—side by side with the more perfected anatomic and physiologic investigations of adult life, which have become the true basis for the enlightened clinical study of human beings.

In order to understand the fully developed man in health and disease, it is self-evident that the anatomy and physiology, not only of the final stage of growth, but also of the various stages of development, from embryo to infant, infant to child and child to adult should be successively dealt with. Looking at the study of pediatrics from this point of view, it is to be noted that the subject is not a specialty, as is that of the eye or ear, but that it is a subject which requires special study, that there is a clinical medicine of infancy and childhood as there is of adult life and old age. One is almost distinct from the other; all are equally important, although it has been held by certain advanced thinkers that the clinical medicine of early life is most important, as it leads up to and influences so greatly that of a later period. In this sense, the study of disease in early life merely represents a large and important division of clinical medicine in general. That the study of the clinical medicine of early life should be taught separately and that it should be promoted by special societies, special journals, special books, special medical departments and special hospitals, is without question, for, as surely as the subject is left to general societies, general hospitals, general literature and general medicine, so will it be neglected and allowed to retrograde. This has been proved over and over again.

With few exceptions, there are no special diseases of children; on the contrary, it is the study of the manifestations of the different diseases as they appear in children which is so important and which shows how different are these manifestations from those of the same diseases as they appear in adults.

WORK OF THE SECTION.

As I look on the members of this Section, representing all parts of the United States, it is impressed on me that it is in your power to develop advanced and general truths; that you should deal in your sectional work with the living questions of the day, and that the results of your deliberations should be authoritatively promulgated by each individual far and wide throughout the whole country. Thus only can the unenlightened influence of the general profession or the laity be curbed in the harm which it is continually doing to the scientific work connected with the early periods of life. Thus only can the self-sufficient ignorance regarding the most critical phase of human existence be properly combated, and the general physician be forced to understand that he has but a limited knowledge of what he has been in the habit of considering simple questions, and on which he has been accustomed to give off-hand opinions and advice to the credulous mother of the suffering child.

---

* Address of welcome given at the opening session of the Section on Diseases of Children of the American Medical Association in Boston, June 5, 1906.

Beyond the important questions of prophylaxis and hygiene, which play such a great rôle in the normal development of young human beings, it is no exaggeration to state that a large number of infants and young children throughout the land are suffering as much from the vigorous and ill-judged treatment of their zealous medical attendants as from the disease with which they started. This should be stopped. This it is the mission of the Section on Diseases of Children to terminate.

NEED OF CORRECT THERAPEUTICS.

The therapeutics of infancy and childhood, as understood by thousands of practitioners in Germany and France, in England and in America, is often a wonderful exhibition of the vagaries in which the human mind, sound on other subjects, can be induced to indulge. There is a total disregard of natural processes, an over-exaggeration of symptoms which in the adult mean danger and require active treatment, while in the child they may be but simple and harmless manifestations of an over excited nervous system. Such is the *ignis fatuus,* so misleading not only to those who have not especially studied the early years of life, but also to those who have seen much of it, but with eyes blinded by traditions of the past.

In this age of rapid progress, of quick change and interchange of ideas, the precision of investigators in all branches of research has almost placed medicine on a level with the exact sciences. It would seem that we, who are endeavoring to place our especial branch on firmer ground, should consider with unusual care the opinions which we express to the profession at large, and to the laity, and that our writings should be founded on principles as accurate as the science of our day can make them.

NEED OF RELIABLE LITERATURE.

This has been but little done, and, consequently, in the last fifty years we have amassed volumes of most unreliable pediatric literature. This is one of the vital living questions of the day, which we should appreciate and grapple with.

The literature of a society gives evidence of the work which has been done by its members long after their individual labors have ceased and their places have been filled by a younger generation. If that literature has been well considered and shows evidence of representing not the hasty judgment of the day, but of being built on the broad foundation of exact science, it will be worthy of the study of our descendants and aid them in their work. As a sound unquestioned nucleus it will give them encouragement to broaden the field of their inquiry and to add new knowledge year by year.

It should be the aim of this Section that a lasting literature of this kind, ever young and fresh in the truths which it enunciates, ever presenting a solid center from which may radiate more extended investigation, shall emanate from its members. Let the papers presented to this Section so teem with unquestioned truths, with pages recording facts and finding small place for theories, that on their face they will prove the truth and not the fallacy of the ancient lines, which, in the present age of unbridled literature, might well be questioned—lines which read:

Give books! They live when you are dead,
Light on the darkened mind they shed,
Good seed they sow, from age to age,
Through all this mortal pilgrimage.
They nurse the germ of holy trust,
They wake, untired, when you are dust.

Gentlemen of the Section on Diseases of Children, I again give you sincere welcome and wish you all success in your deliberations.

POSTCRITICAL FEVER AND OTHER SEQUELÆ OF CROUPOUS PNEUMONIA.*

JAMES E. TALLEY, M.D.
PHILADELPHIA.

A study of the last 325 cases at the Presbyterian Hospital, Philadelphia, forms the basis for this article. Almost naturally one thinks of suppuration somewhere as the commonest cause of the persistence of fever after the crisis in pneumonia, though apparently endocardial and pericardial inflammation is a close second.

Among the suppurative cases we found five of empyema, one being interlobar, one encysted and one genuine case of lung abscess which was large enough to be diagnosed antemortem.

EMPYEMA.

An empyema with typical development as illustrated by the following cases makes the diagnosis easy:

Case 1.—A white woman, aged 47, with typical signs and symptoms of pneumonia involving the lower two-thirds of the left lung, had apparently a crisis (there being a simultaneous fall in temperature, pulse and respiration) on the seventh day, but the temperature immediately went up again, fluctuating between normal and 102 F. The recurrence of the fever, coupled with the fact that though the bronchial breathing and râles in the left chest began to disappear, the percussion note became flat and there was a progressive loss of fremitus, pointed to the presence of fluid there. This, in connection with the fact that the leucocytes which were 17,800 two days before the crisis, increased to 31,600 two days after the crisis, made empyema almost sure. The needle showed pus, and the operation evacuated about two quarts.

Case 2.—This was less characteristic than the preceding case. The patient was a corpulent woman, aged 48, who had had pneumonia at fourteen and several attacks of pleurisy during her life. On admission to the hospital she showed the signs and symptoms of consolidation of the left lung with a friction rub at the base and the squeaking râles of bronchitis on the right. There was no attempt at a crisis, the temperature ranging from 100 to 104 F. throughout the course of the disease with very small diurnal remissions. In addition to the signs in the left chest, the patient developed a somewhat enlarged and tender gall bladder and diarrhea; the Widal reaction was positive, *which made one suspect that the patient was* developing typhoid, as it was prevalent at the time, though a leucocytosis of 36,400 rather negatived the idea. Death ensued on the twentieth day from the chill, and the postmortem showed that the left lung was in a state of gray hepatization, and that the left pleura contained semisolid pus which would not pass through any needle ordinarily used for exploratory tests.

Case 3.—This case of interlobar empyema was in a colored girl aged 13 who had a typical croupous pneumonia involving the whole apex and the posterior aspect of the right lung below. The crisis occurred on the twelfth day with a simultaneous fall of temperature, pulse and respiration. However, though the respirations fell from an average of sixty to the twenties, the pulse rate and temperature did not reach normal. The latter ranged from 100 to 101 and 102 F., which was supposed to be due to a purulent otitis that had developed about the tenth day; but though the otitis improved, the temperature still persisted and made one look for other causes. Three examinations of the sputum on the twelfth, fifteenth and nineteenth days showed pneumococci and streptococci, but no tubercle bacilli. The leucocytosis kept in general about the same level. It was 28,800 soon after admission, 45,200 at the time the otitis was developing, and nine counts from this time until pus was actually demonstrated, showed 32,066. The persistence of leucocytosis, the hectic-like temperature, the continued indicanuria, and the whole aspect of the patient made pus somewhere probable, though the classic sweats and chills were wanting. It was only after aspirating three times that pus was located. The case is reported in full by Dr. Jopson and myself[1] with the reasons for considering it an interlobar empyema, therein set forth.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Case 4.—This case of encysted empyema occurred in a negro teamster of twenty-eight who had his crisis, with profuse sweats, five days from the initial chill, but the temperature soon rose again and remained elevated until death ten days later. He showed on admission signs of consolidation on the left side from the apex to the fifth rib, and posteriorally, over the whole left lung. Also there were some signs of consolidation at the right base. Within a few days the absolute dullness, distinct breath sounds and absence of vocal friction aroused the suspicion that there was liquid in the left upper chest, which suspicion was confirmed by aspiration. The operation evacuated 32 ounces of pus, which immediately accumulated again as shown by postmortem. Also there developed pleural friction and marked consolidation of the right side, and pericardial friction before death.

Autopsy.—The autopsy showed that the left pleura contained one and a half quarts of fluid pus which was encysted in the space from the apex to the seventh rib. The right pleura showed some signs of friable adhesions. The left lower lobe was entirely collapsed and showed one small abscess cavity and several very small abscesses. The right showed a consolidated lower lobe. The pericardium was in a condition of fibrinous lace work, and in a large branch of the pulmonary artery, a long, well organized clot, firmly adherent to the walls and evidently septic in origin, was found.

Case 5.—The fifth case of empyema was in a boy of six, and furnishes an example of the wide-spread changes that may occur in the short space of eleven days counting from the initial chill to death. The attack began with vomiting, chill, fever, and in rapid sequence, delirium, herpes, rigidity of the neck and consolidation of the left base, followed. The temperature remained about 102 F. until three days preceding death, when it fell by lysis to normal and arose again to 104 F. just previous to dissolution. The left lower lobe, and the lower portion of the upper lobe, showed throughout signs of consolidation with a rapid development of absolute flatness and mufiling of respiratory sounds and râles during the last two days of life. The right lung gradually developed signs of consolidation, but never so markedly as the left. Two days before death there developed over the right side, a tympanitic note with a distinct metallic tinkle heard both during inspiration and expiration. The coin test was very marked also, thus pointing to the presence of pneumothorax, probably due to the rupture of one of the small abscesses found postmortem.

Autopsy.—Both the right and left chest showed purulent pleuritis. The pleural cavities were full of yellow pus and many soft adhesions were present. The left lung showed complete consolidation of its lower lobe and a part of the upper. The upper lobe of the right lung contained three abscesses about the size of hazel nuts. The middle lobe contained multiple small abscesses, and a few were also found in the upper portion of the lower lobe.

Though not pertinent to the immediate subject, the markedly contracted colon, and a thin-walled diverticulum on the lower aspect of the greater curvature of the stomach, were interesting.

ABSCESS.

Case 6.—The typical abscess was in a white woman, aged 27, who was admitted to the hospital too ill to give any history except that she had had pneumonia. She was coughing up almost continually large amounts of foul smelling purulent material. Three examinations of the sputum at intervals of several days, showed uniformly that streptococci were abundant, elastic tissue present in small amount, and tubercle bacilli, hematoidin and cholesterin crystals were always absent. The temperature ranged from 100 to 102.3 F., presenting a moderate evening rise and morning fall until the fourth day before death, when it went down by the same remission, to sub-normal.

Examination.—Repeated examinations of the chest showed that the right side appeared larger than the left and expanded more on deep inspiration. From the apex to the third interspace on the right side there were all the signs of consolidation. In this area also were found the cracked-pot sound and amorphic breathing, more marked posteriorally. There were also bubbling râles. Below the spine of the scapula the note was hyper-resonant. The left side was less expansile than the right. Tactile fremitus, percussion resonance, and bronchial breathing all were impaired, but less so than on the right. Especially, below the spine of the scapula were the breath sounds less broncial and more distant. Friction sounds were well developed toward the base.

Heart: The apex beat of the heart was palpable in the midaxillary line, seventh interspace. There was a mitral systolic murmur transmitted and heard faintly in the back. The aortic and pulmonic sounds were heard best to the left of the midclavicular line.

Liver: The liver was a finger-breadth below the costal margin, and there was some tenderness in the right iliac fossa. Two apirations in the usual places on the inner side gave negative results.

X-Ray Examination.—The *x*-ray examination with the screen, showed what appeared to be an empty abscess cavity in the upper part of the right chest, and a filled cavity in the lower part of the right chest. The skiagraph pointed to the same conditions. The autopsy showed that the inference was right about the empty cavity above, but the supposed filled cavity in the lower part was in reality a bronchiectasis in which the bronchial tubes were filled with secretion.

Autopsy.—The right lung, upper lobe, was completely consolidated. A small abscess with thick organized wall on the anterior surface, and a large abscess near the hilum with numerous small metastatic abscesses in the lower portion were found. The middle lobe was normal. The lower lobe was crepitant. There were no nodules. The bronchi were markedly dilated in the lower portion and surrounded with a good deal of fibrous tissue. The left lung showed complete bronchiectasis and atelectasis and obliterative pleuritis, and there were also obliterative pericarditis, dilatation of the ventricles of the heart and some atheroma of the mitral valves, and commencing hypertrophic cirrhosis of the liver.

Case 7.—The second case of single abscess was in a white man who had pneumonia and hemorrhagic nephritis. It was hardly large enough to be diagnosed during life, since it was only about half an inch in diameter, but it had a well-developed encircling wall of fibrous tissue.

ENDOCARDITIS AND PERICARDITIS.

Case 8.—A colored man, aged 25, who had had rheumatism and typhoid fever, developed pneumonia of the right side from the spine of the scapula to the base. There was also a patch of consolidation beneath the left scapula. The crisis occurred on the tenth day, but the temperature rose gradually again to 102 F. and kept elevated for about a month. The heart showed no murmur on admission, but the sounds were dull and the apex was a little outside of the normal position. During this interval of fever, the sputum on several occasions showed pneumococci but no tubercle bacilli, and a blood culture a few days before the crisis was negative. Almost a months after the crisis there was an exacerbation of fever, pain in the left chest with the development of a pericardial friction at the base, and a well-marked systolic and diastolic murmur at the apex with reduplication of the second sounds. Later there was also a pericardial friction at the apex. Still another month later the pericardial friction had entirely disappeared and the endocardiac murmur had improved, though that persisted at the time of his discharge.

---

[1] Archives of Pediatrics, September, 1905.

Case 9.—A white man who said he was fifty, but who looked sixty, had emphysema, myocarditis and atheroma. The fourth day after admission he showed a consolidation of the right apex, and about this time there was acute dilatation of the heart. The apex beat became diffuse, the percussion area somewhat increased and the pulse ran to 200 and above, the rhythm being fetal in type. On the eighth day the temperature fell to normal and remained at about normal for a week. During this time the pulse ranged from 80 to 90. At the end of the week the temperature rapidly arose, reaching 104 F. in the next few days. The pulse ran up from 100 to 140 and became irregular. Then a well-developed systolic murmur at the aortic cartilage, well transmitted into the neck, developed and later this murmur became both systolic and diastolic, with its maximum intensity at the aortic cartilage. The aortic second sound was entirely obliterated, the pulse became of the Corrigan type and the man died on the fifth day from the onset of the endocarditis.

Case 10.—Another case of endocarditis was that of a colored man, aged 23, who had pneumonia on the right side posteriorly with crisis on the eighth day. The heart sounds were perfectly normal on admission. He had a practically normal temperature for six days after the crisis, when there was a simultaneous rise in temperature and development of a roughening of the mitral systolic sounds. The temperature persisted for twelve days and then fell to normal, but the systolic roughening still persisted when the patient was discharged almost a month after its first appearance.

Case 11.—A white woman, aged 20, had a chill and developed at once a consolidation and pleuritic rub at the right base. She had on admission a presystolic mitral murmur which was evidently an old condition. A week after the chill, the signs of mitral obstruction had increased and there had developed an indistinct diastolic murmur heard best over the aortic area. Still a few days later and there were plain signs of aortic insufficiency, as shown by a soft-blowing diastolic murmur faintly heard in the aortic region transmitted down the right side to the sternum, and still heard at the ensiform. The aortic second sound could not be heard. A little less than a month after the onset of the pneumonia, the heart appeared to have returned to its condition on admission; the temperature came down by lysis, reaching normal on the ninth day, and during the days when the roughening at the aorta was developing the temperature was normal or slightly subnormal. Also the endocarditis did not appear to affect the leucocytosis, as the leucocytes on the third, fifth and tenth days were, 23,400, 17,600 and 11,600, respectively.

Two of the cases of endocarditis, one with pneumonia and meningitis, developed a pericardial friction during the course of the disease.

RELAPSING PNEUMONIA.

Case 12.—A colored woman, aged 22, was admitted to the hospital with all the typical signs and symptoms of croupous pneumonia of the upper third of the right lung. On the twelfth day from the onset she had what appeared to be a true crisis, but almost immediately the temperature rose again and at the same time she complained of pain at the opposite apex and gradually developed consolidation of the whole posterior aspect of the left lung. The temperature persisted in her case for five weeks from the onset. The left side was tapped twice, once with no result and once half an ounce of cloudy fluid was withdrawn, which on examination showed no pus. Her mother had died of pneumonia, her father of tuberculosis and during the attack she, herself, gave but a slight reaction to the infection as shown by the mild temperature variations and the moderate leucocytosis ranging from 9,000 to 12,000. However, her sputum was always free from tubercle bacilli and she made a good recovery.

PLEURISY.

Case 13.—A woman, aged 25, with pneumonia of the left base, proved rather conclusively that occasionally persistent pleurisy may be the cause of continued fever after the crisis. She had her crisis on the seventh day, but the friction rubs persisted at both bases, especially on the affected side. A week after the crisis there developed severe pain over the previously consolidated area, which persisted for over two weeks and was accompanied by a temperature of about 100 F. That this was due to the pleurisy, seemed evident from the persistent pain, the disappearance of the previous bronchial breathing, the impaired vocal resonance, the distant breath sounds and from the fact that the screen showed that the area of consolidation had largely cleared up above and at the very base, but that above the base and at the site of the most acute pain, a deeper shadow still persisted.

BRONCHITIS.

Several cases of bronchitis showed a mild persistence of temperature for some time after the crisis which it seemed perfectly plausible to attribute to the bronchitis which existed in the unaffected lung, and in one case in the unconsolidated portion of the affected lung. All the signs and symptoms of the pneumonia pointed to a croupous process. It seems probable that we do not dwell enough on the rôle that a bronchitis, especially in the unaffected lung, may play in the prognosis of pneumonia. Such a condition has seemed to me to be particularly apt to exist in those past middle life who have already an existing heart lesion.

OTITIS MEDIA AND MENINGITIS.

In two cases in the series there was a return or increase of the fever due to otitis. Of course, it is only the obscure cases of ear trouble that are confusing.

Case 14.—A robust man, aged 35, developed a typical pneumonia of the right lower lobe. Headache followed by delirium was an early symptom. One the fifth day from the chill he showed a retraction and rigidity of the neck, and well-developed Kernig's sign. The spinal fluid showed pneumococci and a well-marked to and fro pericardial friction sound at the base of the heart developed the day before death which occurred six days from the onset.

PAROTITIS.

Six years ago I reported[2] a case of suppurative parotitis occurring during an attack of croupous pneumonia in an elderly woman. The first evidence of suppuration was on the seventh day, but so rapid was the development that it discharged on the tenth day. The patient made a good recovery and died, a year later, of interstitial nephritis, which existed at the time of the pneumonia. The number of cases that were reported immediately afterward seemed to show that parotitis as a complication of pneumonia was not so rare as the published cases led one to suppose.

HEMORRHAGIC NEPHRITIS.

Case 15.—A young white man, aged 25, a silver printer by occupation, was admitted with signs of consolidation of both bases, but worse on the right. The urine on admission showed only albumin .05 per cent and hyaline casts, but a few days later there developed evidences of hemorrhagic nephritis—albumin, hyaline, pale and dark granular, leucocytic and blood casts, with some red blood corpuscles, were found. Just when and how the process began is not clear from the history, but the temperature fell from 103 F. to normal the second day after admission and remained at normal or a little sub-normal.

---

[2] Philadelphia Med. Jour., March, 1900.

until death eight days later despite the fact of the small circumscribed abscess in the lower right lobe, and of the nephritis.

Autopsy.—The autopsy showed the right lower lobe solid, the upper half in a condition of gray hepatization, and the lower half in red hepatization. Deep in the substance was an abscess one-third of an inch in diameter, with a well-defined wall. The left lower lobe showed scattered pneumonic areas. Of the kidneys there is recorded only that the cortex was diminished and the congestion of the entire organs, intense. The cultures after the postmortem showed in the heart a mixed culture of colon bacilli and *Staphylococci aurei* in about equal parts. The spleen and right lung showed pure colon bacilli, and the left lung pure staphylococci.

Remarks.—There is much to be desired in the history of this case to determine whether it really was a true case of croupous pneumonia with secondary infection, or whether it was primarily due to the bacteria found postmorten.

THROMBOSIS AND NEURITIS.

Case 16.—A white woman, aged 39, with pneumonia of the left lower lobe had her crisis on the eighth day. Four days later there was a very slight elevation of temperature, and a sharp pain developed in the left leg from the middle of the thigh to the heel. There was no tenderness on pressure, and no disturbance of sensation other than the pain. About a week after the first appearance of the pain, the leg began to show an edematous swelling. The whole history pointed to the fact that it was a femoral thrombosis. This same woman first complained of numbness of the right hand along the course of the ulnar nerve, two weeks after this crisis. Two days later there was distinct numbness of the distribution of the left ulnar nerve. There was some pain, some weakness and disturbance of sensation of both arms and hands. The limitation of the numbness to both ulnars would make one think it was probably due to pressure, but there was nothing peculiar noted about the patient's decubitus at any time, and at the time the neuritis developed, she could be propped up and could soon sit alone. The disturbance was marked enough at one time to require splinting of the right arm and hand. The hands were better, but not well when she left the hospital about six weeks after her admission.

COLITIS.

Case 17.—During the past winter a robust man who appeared to be doing well with pneumonia, was seized with most intense enteritis which resisted all treatment and to which the patient soon succumbed. As a postmortem examination was refused, one can only infer from its remarkable severity, that it was a croupous colitis.

OTHER SEQUELÆ OF PNEUMONIA.

Among the sequelæ of pneumonia that were evident to the naked eye were two cases of carbuncle, one at the back, the other at the neck, which developed in two young white men about a week after the crisis. Both men had good kidneys. A third man of middle life had two abscesses of the chest, one of which might have been due to the single salt injection that he had had, but the other one was so far from the site of the single puncture as to make this cause unlikely.

Case 18.—A white man, aged 40, who drank from ten to fifteen glasses of whisky daily, well demonstrates some of the phases of pneumonia in the alcoholic. His attack began with a temperature of about 100 F. which usually reached normal in the mornings and which persisted for over two weeks. The sputum was bloody and at times was profuse enough to be called a hemorrhage. After two weeks the material expectorated became rather milky white, but showed only pus and no tubercle bacilli. The consolidation was under the right scapula. Ten days after admission he developed delirium tremens, and after the delirium tremens he relapsed into a condition of confusional insanity which persisted for many weeks, but he finally made a good recovery.

Several patients had delirium for a few days after the crisis, which cleared up on forced feeding more rapidly than the delirium in cases of typhoid fever, which often persists for a much longer time because the inanition is greater in consequence of the longer duration of the fever.

SUMMARY.

The causes, then, of postcritical fever in croupous pneumonia are evidently manifold, and the exact cause can be determined in a given case only by careful and repeated examinations of the patient. Even when such examinations are apparently negative one should be slow in attributing the fever simply to delayed resolution or to autolysis alone. The number of small abscesses found in the stage of gray hepatization, postmortem, would incline one to believe that it is not alone the slow resolution, but perhaps more often a varying degree of this purulent tendency, especially in the stage of gray hepatization, that explains the fever. Though the abscesses are usually multiple, one case showed distinctly one small abscess which in itself might have caused the persistence of fever, and it is conceivable that such an abscess may discharge undetected, or, surrounded by an encysting wall, be gradually absorbed and the patient recover without the exact cause of the fever ever being known. Even an encysted empyema, if small, may be hard to demonstrate.

The value of the Roentgen ray in detecting these conditions in the chest is variable. It is the common experience of a thickened pleura in this class of cases that renders the *x*-ray of less value. Given a previous consolidation without much thickening of the pleura and the shadow is less uniformly dense than that of fluid in the pleura, so that under such circumstances a loculated empyema or a full abscess cavity is apt to stand out by its dense shadow in contrast to the less homogeneous shadow of the resolving pneumonic consolidation. Under similar circumstances an empty cavity is even more evident, surrounded, as it usually is, by its wall. One case showed that an area of bronchiectasis, with the bronchial tubes filled with secretion, simulated an abscess. The mistake was all the more natural, as there existed above a well-defined cavity of an abscess that had discharged.

It is doubtful if the number of endocardial and pericardial involvements in this series really represents the vast importance that must be attached to this cause as the factor in many fatal cases. One must be alert for this complication, especially in patients who have an old endocarditis or atheroma. The cases here detailed show that the right side of the heart is by no means free from serious involvement. The development of a systolic murmur may be explained by the anemia well known after pneumonia or by the relative insufficiency due to the weakened heart muscle, but the development also of a diastolic murmur usually means that there is genuine endocarditis, as is proven by the autopsies.

DISCUSSION.

Dr. DeLancey Rochester, Buffalo, said that mediastinal abscess as a course of postcritical fever had twice occurred in his practice. He also wished to confirm the statements made regarding ear troubles. He had two cases of pus in the middle ear without pain and without the presence of pus in the external meatus. In another case he had there was a subdural abscess producing a hemiplegia on the opposite side of the body, but that most cases of postcritical fever were due to empyema of the pleura.

Dr. N. S. Davis, Chicago, said that unquestionably the most important cause of postcritical fever met with after croupous pneumonia is inflammation of the pleura and he believed it to be our duty to search with the greatest care for this cause in out of function, because the man was a right-handed man, and the left clung to life because of its normal 180° axis.

I have a little fellow twenty-seven months old who is wearing B. E. + Sph. 10.00, apparently with almost equal acuteness of each eye. We shall probably find some astigmatism when he is a year or two older. His strabismic eye is now straight, and the glasses are so grateful to his nervous system that the baby yells, *Wo sind meine Gläzele,* if they are left off a minute.

A man of 36 could barely count the fingers with his right eye, and no lens seemed to improve. I stuck to the problem instead of calling it "amblyopia," and I found that — Sph. 6.50 + Cyl. 9.00 ax 10° saved the man's eye and gave him 20/50 vision. This 15.5 D. in a non-traumatic case, at least in one meridian, is the highest I have ever met. There was 6.00 D. in the left, with 20/40 vision.

3. *Inflammations and Traumatisms.*—These may have such organic and irremediable defects in one, or even in both, eyes, that the visual act becomes thereby pathogenic. The most common of these conditions is, perhaps, the nebulous or leucomatous cornea following keratitis. In the young (and the younger the better the success) we may often lessen the opalescence by Pagenstecher's ointment and massage, and other methods of treatment. Unfortunately, Dr. Alleman's proposal of electric stimulation by the contact electrode has not, as was hoped, been adopted or demonstrated of much value.

A profound impression was left on my mind by the history of one patient, a man sent to me by a general physician, with the ready-made diagnosis of "migraine." The man had never had sick headache, so his disease was not "migraine;" the general physician could not cure this patient's headaches, so he sent him to me. I at once notified the physician, 1, that the man never had had "migraine;" 2, that the man's headaches were caused by eyestrain; 3, that in all probability I could not cure the man of his eyestrain headaches. This was because he had a nebulous cornea of the left eye, also a very high mixed astigmatism, giving about 20/50 vision. I ordered glasses, and impressed on the patient the necessity of returning soon and frequently. Pursued by the relentless mystery of his pain, the man fled to the neurologist, who drugged and massaged him without relief; the neurologist then turned him over to the rhinologist, who took out all the turbinates of one side of the nose, saying those of the other side must be taken out, and eventually the frontal sinus opened up "by two holes." The man fled. In this man's case, I shall exclude the left eye from vision, if I can get him out of the hands of the operating rhinologists and the neurologists.

These untransparent corneas almost always cause eyestrain sometimes of a most grievous severity. I fear we greatly neglect to take this fact into consideration, and dismiss without explanations to the patient, and sometimes without correction of the ametropia. In rare cases, possibly the ametropic correction may not, especially at first, give relief; it may more rarely even increase the eyestrain, by stimulating the waning and fading effort and possibility of helpful and useful fusion which must be finally renounced. The problem then becomes most complex and perplexing, and demands the highest judgment and skill to meet it. But purposely to exclude an eye from vision under such circumstances is a hazardous procedure, and needs long pondering. I have not, I think, been compelled to do so more than once, while final success has generally followed ingenuity and persistence to save. I have had one most instructive case which astonishingly proved the wisdom of *nil desperandum.* It was that of a man nearly frozen to death. The keratitis had produced such a dense leukoma, and apparently ruined eyeball that several good oculists advised enucleation, fearing sympathetic inflammation of the other imperfect, but still functional eye. Enucleation was not allowed, and later the better fellow was utterly ruined, and now with the eye pronounced doomed, the man has 20/40 vision and lives a useful life.

Incurable eyestrain is a necessary result of conical cornea.

The adherent irises following neglected or badly treated iritis are often sad evidences of professional ignorance and lack of skill. If occlusion of the pupil is added, not much is left except despair, and "making the best of it." I judge that an artificial pupil generally only adds to the misery. In such cases hope of cure being renounced, the choice may lie between *laissez-faire,* or hastening the exclusion of the eye, or of the cortical center, from participation in vision. But, first, there should be a desperate attempt at ametropic correction, for, with it, nature may keep up the struggle with less pain, and with less eyestrain; even a small degree of vision preserved in one eye, avoids the danger of blows, injuries, etc., upon the blind side of the head. Rents at the corneal border of the iris, causing double pupil, etc., inevitably produce eyestrain until nature excludes the eye from visual influence. Should tattooing sometimes be tried before it is too late? I have one patient with traumatic rupture of the iris, the pupilary edge being attached to the cornea. There is also an undiagnosable irregular astigmatism. The eye is too good to exclude *from vision, and the patient's symptoms are not those of* traction on the adherent iris; they are due to eyestrain, but I can not relieve them. For ten years I treated a patient, one of whose eyes had been ruined by a faulty operation. There were three artificial pupils. I had to exclude the eye from vision until the sensation was dulled and denied.

Cicatrices in or near the cornea from wounds, injuries, and operations, and producing irregular astigmatism, not seldom as we all know, cause eyestrain.

Bungling operations on the lids, entropion, ectropion, etc., have also an influence in making the visual act harder to carry out. One of my patients had a fistulous opening on the cheek through which the tears trickled all her life. It was made by a great surgeon twenty-five years ago in an attempt to open the tear-duct in dacryocystitis. She had had enough of operations, and would not dream of more. "Weeping eyes" suffused with tears are somewhat common, with eyestrain as an inevitable result.

There is in my mind little doubt that the chief cause of senile cataract is uncorrected or miscorrected ametropia. In eyes previously long and properly glassed it does not occur. We all know how incipient cataract often increases eyestrain and necessitates frequent changes in refraction. "The headache of incipient cataract" has become a familiar term. If the cataract is monocular and is advancing, I think it generally advisable to exclude the eye somewhat early. Usually the earliest stages do not affect the center of the pupilary area. When the clear space chosen for vision is at one side of the pupil, eyestrain inevitably follows from the effort to get the macula in line with it.

I have had cases in which vitreous opacities seemed to cause or increase eyestrain. They oftener cause the patient great worry and quacks make much money out of them. Muscæ volitantes do not cause eyestrain, if they are really physiologic, as properly speaking they generally are. One has constantly to calm the fears of patients in reference to them.

Ametropic choroidoretinitis[2] is very common, indeed, almost always exists in long uncorrected ametropia. It is a perfect example of the "vicious circle" of disease, for it is the result of eyestrain, the local effect, and at once it becomes the cause of further eyestrain, both local and general.

Other forms of choroiditis, and of retinochoroiditis, do not usually produce eyestrain unless the macula region is implicated, and unless it has ended in floating vitreous opacities. If one macula is destroyed or badly injured, eyestrain is inevitable until the eye is dulled to functionlessness. If both eyes are affected, the eyestrain must be persistent. I had a patient with both maculas so equally and irremediably hurt that new maculas had formed above the old ones. I sent him to live on a Western ranch, where he is happy.

Tenotomomania usually results in incurable eyestrain. After the muscle-tailor has done his work there is not much we can do, except to apply the proper glasses and wait for Nature's possible undoing of the injury through years of suffering. I remember one patient who had no 'phorias whatever after twenty-eight tenotomies by one graduate tenotomist. The machinery of head and body was largely devoted to getting his head in position to see every degree of change of image. His ocular muscles had been surgically paralyzed.

4. *Amblyopia, or other Injury of Ametropia.*—I have elsewhere published a study of "Amblyopiatrics," or the cure of amblyopia, when it is curable. The majority of patients have some degree of ametropic choroidoretinitis or amblyopia from eyestrain, and the majority of these are entirely curable. In extreme cases it is not curable.

The eyestrain of incurable amblyopia usually depends on the amount of near work done. A young lady patient of mine with 20/40 vision from old uncorrected astigmatism was free from symptoms in her home, but when she went to college there was great suffering. In childhood, in a very few years, strabismus will often render the eye visually useless, even though made cosmetically useful by surgical operation. I had one patient with what I called squint hemianopsia, the temporal half, vertically, of the retina being wholly blind. One may never be sure how much the amblyopia from disuse which follows the eyestrain exclusion of an eye from visual function is due to retinal or cortical causes. And one can also never be sure that the worst cases may not be improved by long and patient amblyopiatric methods.

Some years ago a European physician found a couple of children supposably blind in a blind asylum, who still had some perception of light. He educated this remnant of function, first, in distinctions of light; second, of color; and third, of form, until the children were taught to read and were rescued from a life of blindness. A blind patient over 50 years old has been suddenly brought to perfect physical and sensational vision by operation, but it took some years to perfect intellectual vision. The lesson in all cases of amblyopia is that we should trust Nature and help her by ingenuity and patience to improve amblyopia, and to renounce only when the impossible is demonstrated. I have had but one case in which I had to exclude the eye from vision, because the little improvement possible was a little improvement, and was not further improvable. The influence of dextrocularity in conjunction, of course, with dextromanuality will usually result in the retention of better visual acuity in the right, even with greater ametropia in the right. Nature will always aid more to save the right-eye vision than the left in the dextral.

Accommodationlessness, that is, undeveloped accommodation, may be a result of chronic exclusion of one eye from function for near work, caused, of course, by ametropia. I have had at least three patients whose ametropia was such that one eye was used for near only, and the other only for distance. The latter eye had no accommodational power. If caught early enough in life the defect may be remedied by bifocal lenses. If the patient has passed adolescence, such a device will scarcely prove successful, and the established habit must be permitted to continue; but some eyestrain will also persist. The least intermixture of astigmatism will demand glasses, e. g.,

R. — S. 2.50 — C. 0.50 ax. 50°
L. — Cyl. 0.25 ax. 140°

and fusion will come at once.

Subnormal accommodation[3] is far more frequent than is supposed, and its existence has been a prolific source of many of our past failures to relieve eyestrain. We must be on our watch for it in every patient. None of my successes have been more brilliant or satisfying both to patient and oculist than the half hundred in the past few years, by attention to this most important condition. I now have a child of nine, and another of twelve, wearing bifocal lenses with admirable results. I have found a few cases in which the subnormality differs in the two eyes.

Only the best conscience and the most expert intellect may rightly decide when to persist in stimulating or coaxing an amblyopic eye into use, and when to exclude it.

5. *Heterophoria.*—This cause of eyestrain appears to me refractional in origin and innervational in mechanism, but when it is too high, or of too long standing, it may produce eyestrain, either because too great injury has been done, or because reinstatement of orthophoria is impossible. Preventable all such conditions are, but I have not seen tenotomy of service. In the young if orthophoria is possible, by operation, it is possible by means of glasses, orthoptic exercises, etc. And without proper glasses no operation is useful, because it was the ametropia that produced the heterophoria.

Strabismus has the same law with the exception that its genesis is in childhood, is quickly established, and the irreparable injury sooner completed. With strabismus fixed eyestrain ceases, because Nature has despaired of help, and has renounced effort. Heterophoria is the cry of the dying eye for help; heterotropia is its epitaph. The strabismic death may sometimes be only resignation and coma, and resuscitation still be possible. Undoubtedly we frequently give up the struggle too quickly. But it is murder to delay intervention, as I was taught, until the child should be 7 years old. Such ophthalmology should be put on trial for murder in the second degree. I have cured strabismus by glasses alone in patients over 30 years of age.

In those patients reaching us over 40 to 50 years of age, with high heterophoria, would it be wise to advise operation? I hardly think so. One of the best illustrative cases I have was that of a woman who had 33° of esophoria. I should have lost my patient if I had demanded operation. I incorporated with her ametropic correction 13° prisms in each eye for distance, and 7° for near, and she has never for years had enough discomfort to make her think of operation. By a marvel of the optician's art her lenses are not very heavy or unsightly.

6. Interruptions or Contradictions of the Normal Coördination of Dextrocularity and Dextromanuality.—When traumatism, inflammation or other cause conflicts with or extinguishes the established coördination of dextrocularity and dextromanuality so that the left eye (in the dextral) must take up the proper dextral function of the right, eyestrain, at least for a time, almost inevitably results. There is an awkwardness, indecision, slowness, etc., of action, thought or vision, probably of all three, which may be more or less lasting. I have had a number of such cases, but the particulars are too numerous to find room here.

7. Cerebral or Nerve Disease Occasionally Causes Eyestrain.—Paralysis of accommodation, not from peripheral causes, but from cerebral ones, may exist, overlooked, in one or both eyes. Some eyestrain will still exist even with bifocal lenses. Failure of detection may be caused by the cycloplegia and may be present without a noticeable mydriasis. I have had a number of such cases.

Permanent myosis may cause incurable eyestrain because of evident optical reasons. I had one such case in which a famous neurologist could find no evidence of neurologic disease to account for it, and we both failed to bring about any alleviation of the symptoms patently eyestrain in nature. I had a theory that the myosis in this man's case was due to a tiny corneal opacity in the center of the pupil. My neurologic friend scorned such a philosophy.

Slight nystagmus, with small and almost undetectable excursions, flutterings, or tremblings, may, as will be readily understood, produce eyestrain. In one patient, a woman of 50, there was the most rare symptom of rotary nystagmus, which no glasses could cure. And I have had one case of monocular nystagmus that to some degree caused incurable eyestrain, although the young man had only 3/200 vision in the affected eye. Possibly the diplopia of paralytic strabismus may not be properly classed as eyestrain, and yet in one sense it is so. I have had to put two such eyes out of function by a steamed or ground glass, so slightly obscure as not to attract attention, and which at the same time would not allow vision.

There is no evidence that color blindness may coöperate in producing eyestrain, but it is possible that it may do so. Certainly in the beginning stages of optic atrophy there would probably be such an effect. I have reported a remarkable instance of hereditary optic atrophy occurring only in males, transmitted only by females, taking place from 28 to 34 years of age, and running through six generations. While the disease was in its early stages and ingravescent, one of these patients had decided eyestrain symptoms, not to be relieved by any means, of course.

I have had several patients in whom tremor of the head was a source of eyestrain.

I recently discovered one of the most unsuspected ways in which a disease of the central nervous system may produce eyestrain. I have no doubt that my little report is so far unique. My glasses had failed, in part, to relieve in a woman of 40 the symptoms of decided eyestrain in reading, not in writing. There was no subnormality of accommodation or other discoverable cause of the perplexing fact, until I noticed that her hands had a rapid and constant tremor. I placed her newspaper or magazine against a solid body, or in a book-rest, and the shivering was stopped, which caused ocular tiring.

8. Disease of the General System.—This condition, affecting directly or indirectly the nutrition or functions of the eye, may sometimes have some effect in causing eyestrain. This factor has been so ludicrously overemphasized in the past that it needs no more than mention here. Many "conservatives" who care nothing for scientific refraction problems have practically thrown the baby away with the bath, and have really sought to resolve all eyestrain into systemic disease. Although 99/100 of their contention is ludicrously untrue, there is, nevertheless, a possible 1/100 of truth in it. Although diseases of the nose and accessory organs may rarely affect the eyes, the rhinologist, and surely the operative rhinologist will have little work to do when the enormous influence of eyestrain on the nose is recognized. Much the same may be said of the gynecologist, the celiotomist, the gastrologist, and even the general physician.

9. Eyestrain Due to Unhygienic Occupation, Use, or Abuse of the Eyes.—In our offices we have constant evidence of these causes. Most of these cases are obviable or remediable, and their consideration goes over into the chapter on hygiene of the eye. This is indeed a chapter which, speaking resolutely, still remains unwritten, and which, when written, will not become popular reading for a century. During this waiting-time millions of eyes will be ruined, and vast reserves of health foolishly wasted. But in a minority of cases we find ourselves unable to prevent eyestrain, so plainly present. I have often run across the prejudice of employers, school trustees, and especially of railroad officials, against spectacles, even though the employé suffer and the lives of trainloads of people are jeopardized. The trainmen or switchmen say that the superintendent will probably "lay them off" as too old, whether presbyopic or not, if they show themselves in glasses. We should manage to convince the officials of the double folly of their ways.

Half of the clerks, stenographers, bookkeepers, etc., are compelled to carry on their work with poor lights, wrongly placed lights, etc., and when the lighting of their desks is good, the employé himself omits many other wise measures preventing eyestrain. Our school desks and commercial desks are universally flat, but when ophthalmology becomes ophthalmologic, and when civilization becomes civilized, they will be made sharply pitched. The unphysiologic, unophthalmologic, outrageously stupid writing posture of the occidental world begets a big deal of eyestrain, and most of the lateral spinal curvature which curses 27 per cent. of our school children. That we look sharply downward on our writing, etc., instead of off, from, and slightly downward, that we pathogenically angle our paper, are other sources of eyestrain, which we shall long and vainly struggle to change.

There are many other occupations which variously contribute to the conditions of eyestrain.

Lastly comes the fact on which is based the whole theory of the origin of eyestrain, namely, the impossibility of the long and continuous innervation and contraction of any single muscle or set of muscles in the human body. Rhythm is the law of life, and surely of muscular contractility. The modern human eye is often put to tasks which it is incapable of carrying out. Normalized accommodation (that is, accommodation without any ametropic morbidizing), is in fact always subnormal, when it is required to be executed with scarcely a break or change for hours, almost a whole day, and for all days of the year and life. Nature never made the eye for such work, and has not outfitted it with an adequate mechanism.

DISCUSSION.

Dr. Peter A. Callan, New York, said that while Dr. Gould emphasizes the effect of glasses, the use of atropin and the shutting out of one eye, he totally ignores the operative side. Dr. Callan does not think that ophthalmology consists alone in the fitting of glasses; it is something broader than that. He said that when Dr. Gould spoke of the treatment of congenital cataract by the use of atropin he probably meant lenticular pigment spots in the area of the pupil and not the kind of congenital cataract which is generally spoken of as such in which the anterior posterior pole of the lens is affected. Dr. Callan said that it would have been better to consider the best means of treating these cases surgically. Dr. Callan thinks that the mistreatment of iritis in the hands of most men is due to the patient not carrying out instructions. Many times he has been obliged to insist that patients go to the hospital in order that the treatment be properly carried out. Dr. Callan mentioned Dr. Gould's reference to an operation for occlusion of the pupil and said that if Dr. Gould means total occlusion of the pupil it is the imperative duty of the physician to operate. Last year Dr. Callan saw a child of 10, with pupils occluded, who was being educated in an asylum for the blind. He performed an iridectomy and the child is now pursuing its studies in the proper way. He said that Dr. Gould may be right in saying that these patients can not be treated by glasses, but that is no reason for subjecting them to life-long misery when operative measures may give relief.

Dr. Callan declared that one might as well claim to prevent gray hair by the use of glasses as to prevent cataract. If one lives long enough there will be haziness of the nucleus, and, though patients are fitted with the best possible correction, they will eventually develop cataract, and it can not be prevented.

He said that no one appreciates more than he does the good that Dr. Gould is doing in his ophthalmologic writings, but for a teacher to cast slurs on the medical profession and to ignore, as he does, the benefits of operative procedure, Dr. Callan thinks is uncalled for.

Dr. Louis Borsch, Philadelphia, referred to Dr. Gould's ninth cause of eyestrain due to use or abuse of the eyes, in which he cites cases of patients straining their eyes by not wearing glasses, because glasses make them look old, and said that there are many more people who abstain from wearing glasses and thus fatigue their eyes than one would at first be inclined to suppose; especially is this true when the oculist prescribes bifocals, for bifocals are popularly supposed to mark a person's age. Dr. Borsch said that when glasses or bifocals are not worn when required, eyestrain results. On the other hand, very often when they are worn strain results that is just as severe, and this is due to the improper construction of these lenses, as most of them are unsatisfactory. For some years he has been endeavoring to devise a lens which would embody all the desirable features of a bifocal from the oculist's, the optician's and the wearer's point of view. These desirable features are as follows: (1) A bifocal lens having the least perceptible line of junction between the near and far portions of the lens; (2) having no prismatic displacement; (3) having no cement to become loose or cloudy; (4) having the optical and geometric centers corresponding with each other; (5) what is of no little importance, a lens that can be made by any lens grinder and at so modest a cost as to be within the means of any one requiring bifocals to gain a livelihood; (6) a bifocal that won't make the wearer look old.

This he has successfully accomplished, and he exhibited this new bifocal, which consists of two pieces of optical glass of different indices of refraction welded together in an electric furnace, thus making a solid piece of glass.

Dr. George M. Gould, Philadelphia, said, in reference to improperly treated iritis, that we all know that 75 per cent. of the cases are not treated by ophthalmologists. It is a great mistake to think of the profession as consisting of a few excellent ophthalmologists in the cities. A great number of the patients are not seen in the cities, and even there how many cases of iritis get into the hands of the oculist? In regard to the cause of cataract he said that Dr. Risley has long contended that it is due to choroidal disease, and Dr. Gould contends that choroidal disease may be due to eyestrain. He has never seen a patient who had worn proper glasses develop cataract. He does not ignore operations at all. When they are indicated and required, of course, they are to be performed. His remarks referred to cases in which operations are not indicated. As to maligning the profession, that is "tommyrot." It is the patient who must be cared for without regard to injury to our special or professional pride.

AN ANTISEPTIC TREATMENT OF TUBERCULOSIS.

H. H. MALONE, M.D.
AUGUSTA, GA.

In the treatment of tuberculosis we have to deal with tubercle bacilli, on the one hand, and the human being on the other. The quantity of powerful drugs daily taken by those unfortunates who have acquired the drug habit demonstrates the power of the human organism to accommodate itself gradually to changed conditions. It appears reasonable to suppose that if powerful poisons, such as chloral, cocain, arsenic, morphin, etc., can be tolerated by the human subject in gigantic quantities, then a like tolerance can be created for certain other drugs of less toxic influence, but possessed of bactericidal properties.

Through a tolerance thus acquired it may be possible to administer such germicidal substances in quantities sufficient to inhibit, damage, or even destroy pathogenic bacteria, such as tubercle bacilli, within the body, and to do this without injury to the human body. This hypothesis presupposes the lack of a similar or at least equal tolerance acquired by the bacteria under these circumstances.

TUBERCLE BACILLUS AND GERMICIDAL AGENTS.

The tubercle bacillus is restricted within a comparatively narrow range of environmental conditions for its growth and other vital activities. Many low forms of vegetable life do not possess an accommodative power equal in degree to that of the higher forms of animal life. In general the human body does not offer favorable conditions for the multiplication and pathogenic activities of the tubercle bacillus, and when such conditions of the human body exist they can by proper measures often be rendered unfavorable for the bacillus. The tubercle bacillus is sensitive to the addition of even small quantities of antiseptic substances to media otherwise favorable for its cultivation, and we have no experimental proof that through the gradual addition of increasing quantities of an antiseptic the bacillus can acquire a tolerance of the toxic effects analogous to that acquired by a human being to certain drugs. When placed in a culture tube under suitable surroundings, and a sufficient quantity of a given antiseptic is added, destruction of the tubercle bacilli results. It matters not how gradually the antiseptic is added; it is only requisite to introduce a certain fixed amount to accomplish the death of the bacilli.

By the judicious introduction into the human system of certain antiseptics proved to be destructive of the tubercle bacillus, great quantities may be ingested without apparent injury to the human tissues, and, it would seem, enough to injure, if not to destroy, the tubercle bacilli. This result is probably attained not solely by the direct germicidal action of the antiseptics used, but also indirectly by the change in the environment of the bacilli and increased efficiency of the defensive forces of the body in combating the germs and their effects. If a patient afflicted with tuberculosis weighs 130 pounds, about one-thirteenth of this weight, or ten pounds, is blood. The introduction of seventy grains of an antiseptic into the circulation would result in a ratio of one part of the antiseptic to one thousand parts of fluid, a concentration fatal in the case of certain antiseptics to many bacteria.

While, of course, we must consider many other factors than the percentage of the antiseptic in the blood, such as its further diffusion in the lymph and tissues, its possible decomposition and rapid elimination, irregularities in its distribution in different parts, still, in view of such considerations as those stated, it does not seem to me to be so hopeless a matter, as is often assumed, to secure direct injury and probably actual destruction of tubercle bacilli within the body by the administration of suitable germicidal substances in requisite amounts, and this without harm to the cells of the host. We have, furthermore, the advantage of being aided by the leucocytes and other vital forces of the human body, and of the fact that the circulating and other fluids of the human body are not so suitable a culture medium for tubercle bacilli as the culture fluid of the laboratory test tube. If I have reasoned correctly, we have now arrived at the point of selecting the most suitable antiseptic or combination of antiseptics.

IODIN AND PHENOL.

We have reason to believe that iodin is a powerful antiseptic, and, in addition, promotes constructive metamorphosis under certain conditions which are usually present in tuberculosis. Iodin is absorbed in combination with alkalis and probably with proteids, and has long been used in the treatment of tuberculosis, although the mode of its action is not well understood. One of the most powerful and generally useful antiseptics, especially in the presence of albuminous material, is phenol, which, furthermore, lessens the irritative properties of iodin and permits administration of the latter in larger doses. In addition to its valuable effects on iodin, phenol, we find, possesses the property of destroying most organized ferments of animal and vegetable life. It is admitted that bacteria and moulds are readily deprived of their characteristic power by solutions of phenol, whilst chemical ferments (enzymes), such as pepsin and ptyalin, are much less readily affected. Some authorities claim that chemical fermentation is entirely prevented by strong solutions of phenol. However this may be, I have found that patients taking daily more than one dram of phenol gained weight for fourteen consecutive days. Hence, phenol under certain conditions also promotes constructive metabolism.

Phenol, like iodin, has irritating and caustic properties which can be materially lessened by proper dilution, and still further by the action of camphor, which is also an antiseptic, and which renders it possible to attain the maximum dose of phenol in the minimum time. Phenol passes through the tissues unchanged for the most part, although a certain part undergoes partial oxidation. The etherial sulphates in the urine are increased, while the ordinary inorganic sulphates are diminished and may disappear. The olive-green discoloration of the urine, familiar to those who misuse the drug, bears no definite relation to the amount of phenol in the blood, nor to the danger of poisoning. The discoloration may be produced by a small amount of phenol, while very much greater quantities make no change in the color of the urine.

By gradually increasing the dose, far greater quantities of carbolic acid may be given to advantage than the authorities would lead us to believe. It has recently come to my attention that as much as twelve to fourteen grains have been administered at a dose every two hours in the treatment of influenza by Wigglesworth, and of plague by I. M. Atkinson,[1] presumably from the start, but my own experience justifies the belief that much better results are obtained by beginning with smaller doses. There are a great many cases of tuberculosis in which such large doses can not be endured from the start, owing probably to functional inabilities of certain organs. It is the injudicious method of using the drug which is responsible for its evil effects.

For many years these drugs have been recommended in the treatment of tuberculosis with uniformly negative results, probably because they were not combined so as to deprive them of some of their evil effects, and consequently they were not pushed to the point essential to accomplish the desired results. In this connection it is interesting to note, in addition to the beneficial results reported by Wigglesworth and by Atkinson, the successful results obtained by Bacelli and Ascoli in the treatment of tetanus by phenol, and by Dr. Quill in the treatment of typhoid fever with a mixture containing phenol and spirits of chloroform.[2] Considerable misapprehension doubtless exists both as to the dosage and as to the toxicity of carbolic acid, a misapprehension based on the cases of poisoning resulting from its external use, or from its administration in too concentrated form. There are unquestionably individual idiosyncracies as regards susceptibility to carbolic acid, but I agree with the authorities cited in the opinion that in proper combination and in proper dilution carbolic acid may be taken internally in far larger doses than have been customary. I, furthermore, believe that a measure of tolerance may be established by gradually increased doses.

DOSAGE.

The doses essential to accomplish the desired results are in conflict with the teachings of recognized authorities, but the results obtained demonstrate the value of the deviation from the accepted teachings. From what some might consider undue quantities, observations failed to reveal any derangement or morbid change in function or structure of any organ or tissue.

The formula which I have successfully used is as follows:

Phenol	m. 160	11
Spiritus of camphor	ʒ 3½	14
Tincture of iodin	m. 160	11
Glycerin C. P.	℥ss	15
Cherry laurel water		
Chloroform water		
Cinnamon water		
Tar water, of each enough to make	℥ 15	450

Mix and allow to stand until all free iodin disappears, then make an emulsion by adding one ounce, each, of cod liver oil and powdered acacia. Begin by giving one teaspoonful in a half cup of water every four hours, and gradually increase the dose to a tablespoonful at intervals of one hour. Should it become necessary, a stronger solution may be substituted here, or the quantity may be further increased, depending on the weight and tolerance of the patient. Technic plays an important part in the management of each individual case.

---

[1] The Lancet, 1899, vol. i, p. 958; also 1899, vol. ii, p. 1589, and 1903, vol. ii, p. 754.

[2] Potter: Materia Medica, Pharmacy and Therapeutics, tenth edition, p. 381.

MODE OF ACTION.

As to the precise mode of action of each of the principal ingredients of the foregoing formula, it would be unwarrantable to make too positive statements. I incline to the opinion that there is a combination of direct antiseptic action on the bacilli with a favorable influence, exerted particularly by the iodin and the camphor, on phagocytosis and other protective agencies of the living body. The leucocytes are increased in number, and the symptoms indicate neutralization of toxins or cessation of their formation. An interesting phenomenon is the darker staining of the tubercle bacilli by carbolic fuchsin in the sputum of patients under this treatment.

I reserve for another occasion the detailed report of the results of the treatment, but these results as regards disappearance of the bacilli and increase in weight of the patient, and in a number of instances of even advanced pulmonary tuberculosis as regards apparent arrest of the disease and restoration to health have been so favorable that I desire to place in the hands of the medical profession the opportunity to make trial of the treatment.

While I have been led to the adoption of the treatment partly by hypothetical considerations, which I have set forth, of course, the essential test of its value must rest on facts accumulated by experience, independently of the correctness or error of the hypothesis.

NASAL DISEASE AND NEURALGIA.*

LEWIS S. SOMERS, M.D.
PHILADELPHIA.

The intimate relation existing between headache, migraine and neuralgia at times renders the differentiation of one from another of considerable difficulty, but as it is desired to consider only the latter in relation to nasal disease one must clearly appreciate what is meant by this term.

A comprehensive definition is: "Neuralgia is pain in a nerve or nerves, or radiating along the course of a nerve, of a severe, darting or throbbing character, intermittent, with sensitiveness of the skin and tender points where the cutaneous branches are given off from the deeper parts."

As with headache, the nose is a frequent and yet unrecognized cause of many cases of trifacial neuralgia, and, while it is not desired to imply that nasal and accessory sinus diseases are the most frequent factors in its production, yet they play an important rôle. Hence in all such cases of neuralgia these parts should be carefully examined, a procedure which, unfortunately, is rather the exception than the rule.

As both the nasal interior and its accessory sinuses are supplied with sensation by the trifacial nerve and its branches, and as this nerve is more frequently the seat of neuralgia than all other forms combined, it is evident that affections of these structures should not only involve some branches of the nerve reflexity, but, still more important, directly, and this occurs in many cases of trifacial neuralgia when no apparent cause is evident, because these structures are not investigated or are entirely neglected. Corroborative evidence of this is shown in cases in which, after operation in the nasal interior, neuralgic pains are observed along various filaments of the superior maxillary branches of the trifacial nerve, radiating into the teeth of the upper jaw and through the mucous membrane of the buccal surfaces. In common with neuralgia from any cause, that form resulting from disease of the nasal chambers, shows periodic variations in its intensity, in many instances being influenced by pressure between adjacent tissues, but there is usually no definite relation between the focus of disease and the seat of pain, it being not uncommon to find neuralgia in various portions of the head in cases of the same affection, in some instances the pain being on the side opposite to the nasal lesion.

The seat of pain in the individual case is practically constant, and unless additional tissues become involved in the morbid process it is unusual to find the original neuralgia changing its position, but in severe cases one finds, when a main branch of the nerve is involved, that the pain extends in a greater or less degree to other branches. While facial neuralgia frequently results from various nasal affections, but irrespective of the particular nerve which is the seat of the neuralgic process, the type differs in no way from that produced by other causes, either in the nose or sinuses or elsewhere, and from this aspect the basal cause can not be differentiated without obtaining the added light afforded by further studies of the particular case.

Nasal neuralgia, *per se*, that is, neuralgia limited to the nasal structures, does not necessarily follow from disease here, but may be the result of changes in other regions, such as alterations in the Gasserian ganglion or the various nerve trunks emerging from it, when pain may be complained of in the nose in addition to supraorbital or temporal neuralgia. It is also essential to bear in mind that the nasal interior may be abnormal, yet the neuralgia be the result of changes distant from this region, as it has been shown that in primary trifacial neuralgia catarrhal alterations of the nasal mucous membrane are not infrequent as a secondary result; and if care be not exercised these alterations may be mistaken for the cause of the neuralgia and not properly interpreted as one of its results.

So far as the accessory sinuses are concerned, acute sinusitis, and less frequently chronic changes, are a frequent cause of neuralgia and often the excessive pain is considered both by the physician and by patient as the actual disease itself. The character of the pain not infrequently adding to this erroneous impression, as it may last for a week or more with partial intermissions, and then severe exacerbations, the former being ascribed to the analgesics prescribed, with later subsidence of the pain, often accompanied with a purulent nasal discharge, may lead to the correct interpretation of the cause as an attack of acute sinusitis and not, as was believed, an idiopathic neuralgia. In acute inflammation of the sinuses, neuralgia is a frequent symptom, especially supraorbital pain of a throbbing and pulsating character. This location of the neuralgia is the rule, while pain in other regions of the face and head is more or less exceptional. As a presumptive sign of sinus empyema, neuralgia should be given considerable credence, but at the same time it is a deceptive sign and a most irregular one, as it may or may not be present and is rarely localized by the patient with any degree of certainty, although when found in the region of any particular sinus, especially when palpation increases the pain, it may be a symptom of considerable value in detecting the original focus of the trouble.

---

* Read before the Kensington Branch of the Philadelphia County Medical Society, May 8, 1906.

NASAL NEURALGIA.

As a type of pure nasal neuralgia, the following case is illustrative:

CASE 1.—Mrs. I., aged 23, had left supraorbital neuralgia for four years, with severe attacks at intervals of from a week to ten days and often lasting for three days without relief.

After much treatment with no result, she came to me for nasal stenosis which had not been considered as bearing any relation to the neuralgia. The left inferior turbinate was hypertrophied and jammed against the septum and following removal of its inferior border, which was the only treatment adopted, the neuralgia disappeared as soon as the pressure was removed and has not returned in three years.

HYPERTROPHY OF THE TURBINATE.

Of all the affections involving the nasal chambers independently of sinusitis, hypertrophy of the turbinates, and especially of the middle, is the most frequent cause of neuralgia. Both supraorbital and facial neuralgia result from continued pressure of the middle turbinate against the septum, the former resulting from pressure on the nasal branches of the fifth nerve, which may be greatly enhanced if there is, in addition, sinus involvement. The pain of intranasal pressure may be referred to the eye, to the frontal region or to the nose itself, and occurs with hypertrophy of the posterior part of the inferior turbinate, with synechia or spurs of the septum of sufficient size to cause pressure against the opposite tissues. Neuralgia also occurs in acute rhinitis from excessive congestion and intranasal swelling, but more especially when the sinuses are coincidently involved, and then there may be hammering, piercing pains of the supraorbital region, often synchronous with the pulse beat. In the later stages of the same condition, when there is a purulent discharge with obstruction, and especially when deviation of the septum in its upper portion exists, transient neuralgic pains are not infrequent. Of the other conditions in which this symptom is sometimes a feature, hay fever and intumescent rhinitis require mention, as in the former neuralgic pains of the eyeballs, root of the nose and rarely of the occipital region are not infrequent when the attack is severe, while in intumescent rhinitis, hemicrania or neuralgia of the supraorbital, occipital or temporal regions is often part of the disease.

Slight irritation of the nose may produce a degree of nervous instability sufficient to cause severe neuralgia, yet in the majority of cases in which pressure is continued actual nerve changes are undoubtedly produced; the case reported by Lermoyez demonstrates this in a convincing manner. A myxomatous degeneration of the inferior turbinate was removed with the cold snare and galvanocautery, and this was followed in three months by free nasal respiration, but also with severe supraorbital neuralgia uninfluenced by drugs. The scar on the turbinal tissue was then removed, with permanent disappearance of the neuralgia, and microscopic examination showed that a nerve fiber engaged in the cicatrix was acting as the pathologic basis for the pain.

MAXILLARY SINUSITIS AND NEURALGIA.

As an example of neuralgia resulting from maxillary sinusitis, the following case is suggestive of nerve implication:

CASE 2.—Mrs. H., aged 32, had been operated on through the canine fossa of both sides for antral empyema, two years before she came under my observation. The anterior end of the inferior turbinates had been removed and free drainage of the sinuses was obtained by large openings into the external nasal wall of each side. For the past year she has suffered constantly from infraorbital and supraorbital neuralgia.

Examination eliminated other sinus involvement and pointed to nerve implication from necrosed bone in the maxillary sinus walls. This was verified by curetting the softened bone areas, so that following this the neuralgia was no longer a source of annoyance, although a mucopurulent discharge still persisted. A few months later neuralgia recurred on the left side and that sinus showed further caries of its walls, but no further measures have been taken to remove the diseased bone.

The incidence of neuralgia from the maxillary sinus is probably not so common as that from the frontal, although the nerves are more exposed in the former, but its physical conformation is such that pressure of retained morbid secretion is rather infrequent compared with similar conditions of the frontal sinus. Infraorbital, supraorbital and dental neuralgias are not unusual in acute and chronic maxillary sinusitis, and when present are of presumptive value in suggesting antral disease, frontal neuralgia being most common, but any severe facial pain should direct attention to this sinus. In acute inflammation, the pain is often mistaken for simple neuralgia, as it is apt to involve the teeth and to extend into the temple and is a common symptom. In chronic empyema of the maxillary sinus, however, neuralgia is not so frequent, but when present it may involve half of the head, like migraine, or intense pain may be complained of over the facial surface of the superior maxilla. It is often periodic in intensity, increasing in degree for several hours, then diminishing and frequently disappearing later in the day, to return again in the morning. In such instances the neuralgia is a direct symptom of nerve irritation from inflammation of the mucus lining of the sinus, the superior dental nerve running along its walls, and it is not infrequent to find the thin bony covering dehiscent in some areas, so that from the superficial position of these nerves the pain is referred to the nerve trunk and intense neuralgia may result. In some cases this may not be so severe, but there will be points of tenderness over the nerve and especially at the point of exit of the infraorbital nerve.

FRONTAL SINUSITIS AND NEURALGIA.

Acute inflammation of the frontal sinus is always accompanied with headache and not infrequently with severe neuralgia. The following case illustrates this feature:

CASE 3.—Miss N. aged 21, following an attack of acute coryza, developed violent right supraorbital neuralgia which was continuous and prevented her from sleeping.

She was seen after the neuralgia had lasted for three days and analgesics had failed to give relief. Examination showed acute right frontal sinusitis with retention of secretion and the slightest pressure over the supraorbital nerve caused exquisite pain. After reducing the swelling of the frontal canal with cocain and adrenalin, a profuse discharge ensued on this side and relief was immediate, the remaining tenderness over the sinus disappearing in a few days.

In all forms of frontal sinusitis, whether due to congestion of its mucous membrane accompanying acute rhinitis or resulting from pus retention of chronic empyema, supraorbital neuralgia of the affected side is frequently observed. It differs in no way from the frontal neuralgia found in many affections, as the pain may be paroxysmal, often periodic and extending toward the occiput; at times it annoys the patient only slightly, again it is excruciating, and the usual medicinal measures used for neuralgia are utterly without value. The pain may be bilateral, but it is more frequently one-sided, and there is tenderness to pressure over the exit of the supraorbital nerve and the lower anterior wall of the sinus. Often in chronic frontal sinusitis when unrecognized, the neuralgia may last for years with variable periods of freedom from pain, the condition usually being considered as one of simple supraorbital neuralgia. Infrequently the pain is in the occipital region, and then mistakes in diagnosis are still more apt to occur. The relation of the supraorbital nerve to the frontal sinus explains the frequency of neuralgia here, as its branches ramify over the anterior and inferior walls and the inflammation of the mucous lining involves the nerve trunk, while, when the sinuses are small, so that retained secretions are under pressure, it can readily be understood that neuralgia must be frequent.

ETHMOIDAL SINUSITIS AND NEURALGIA.

More often productive of headache, empyema of the ethmoid cells may be the exciting factor in occipital and frontal neuralgia, as the following case demonstrates:

Case 4.—Miss G., aged 20, had ethmoid suppuration on both sides, with enlargement of the middle turbinates and pressure against the septum. In addition to almost constant headache, attacks of occipital neuralgia occurred every week or so and incapacitated her for work, while frontal neuralgia was less frequent but unusually severe.

Since removing the middle turbinates in part and curetting the necrosed ethmoid cells for an irregular period of over two years, no neuralgia has been present for three years, although a mucopurulent discharge is at times annoying.

Unrecognized ethmoid disease, with or without neuralgia, is usually treated as postnasal catarrh, or, when neuralgia is severe and frequent, it is often treated as the sole disease and not as a symptom of the causal affection. Supraorbital, occipital and basal neuralgia occur in many cases of ethmoid empyema in which pus is confined under pressure in the various cells of this region, while in open ethmoiditis without obstruction, pain is usually not complained of, or at the most headache may be present to some extent. While it is suggested that empyema of the middle and anterior group of cells produces facial and vertex neuralgia, and that of the posterior cells vertical and occipital pain, yet in the majority of cases this is far from the fact, as it may involve the root of the nose, the lower inner angle of the orbit, the frontal region and the upper part of the cheek, but as a rule the localization of neuralgia from ethmoiditis is vague and in no way characteristic. The basal type of headache or neuralgia should suggest an examination of these sinuses, for in some cases the pain is on a plane with the base of the skull, involving the back of the eyes, the mastoid and temporal regions and the occiput along the same level. In other cases, infrequently observed, there may be a point of tenderness externally between the nasal bone and the lateral cartilage, where the anterior ethmoidal nerve sends an external branch to the skin covering this region.

SPHENOIDAL SINUSITIS AND NEURALGIA.

The least recognized of all these affections are those of the sphenoid sinus, and while empyema here is accompanied with headache more frequently than with neuralgia, yet the latter may occur, as shown by the following case:

Case 5.—Mrs. M., aged 55, has had a postnasal discharge for twenty years and once or twice a month intense neuralgic pains over the entire head, originating from a center situated at the intersection of two lines, one horizontal from the base of the nose, the other vertical from the top of the head. Five years ago the anterior wall of the sphenoid sinus was opened and since then the discharge has materially lessened, while the neuralgia occurs about once in two months, the attacks being as severe as before.

When I first saw her the trouble seemed to be entirely in the sphenoidal sinus and the opening had become obstructed so that retention of secretion caused the neuralgic attacks, while so long as the discharge was small in amount and there was no obstruction to its exit she was free from neuralgia.

In acute sphenoidal sinusitis, neuralgia may involve the frontal and occipital regions and produce intense agony, the pain also being complained of deep in the center of the head. In chronic empyema, however, while the pain may not be so severe, in some instances much suffering may be produced. Its location varies, but not infrequently the eyes are painful, the supraorbital nerve is involved or the pain may be over the vertex.

COMBINED SINUSITIS AND NEURALGIA.

The last case which I desire to mention illustrates a frequent condition, in which there is combined sinusitis and marked intranasal changes:

Case 6.—Miss R., aged 22, complained of a profuse mucopurulent nasal discharge and basal neuralgia, especially severe over the supraorbital regions. When the neuralgia was not present there was a dull headache. The middle and lower turbinates on both sides were swollen and jammed against the septum, while the ethmoid, sphenoid and frontal sinuses were involved, no evidence of antral disease being obtained. As the result of several months of treatment, the headache entirely ceased when the obstruction and pressure had been removed; the supraorbital neuralgia also disappeared and the attacks of basal neuralgia diminished both in frequency and severity. The ethmoid sinusitis which has not entirely disappeared under treatment causes occasional attacks of pain.

The neuralgia observed in such instances is bizarre and exceedingly confusing, and one can never be certain of its relation to any particular changes in the nasal chambers or sinuses until the affected parts have been approximately restored to normal, the retained secretions evacuated and pressure between opposing points has been removed. When during acute coryza or grippe, especially, the location of the neuralgia apparently bears some relation to a particular sinus, one may take it, with many exceptions, however, as an indicator of involvement of that cavity, but on this alone the diagnosis of sinusitis can never be made with certainty, nor can the relation of cause and effect be disclosed without more certain corroborative evidence.

In frontal or sphenoidal sinusitis, persistent occipital neuralgia may be a marked feature, or in either of these, with pathologic alterations of the ethmoid cells, neuralgia localized in the supraorbital or infraorbital regions, with marked tenderness of the orbit, is not infrequent. It must also be borne in mind that in many cases of neuralgia in which there is intranasal or sinus disease it does not follow that the former is dependent on the latter, for no relations at all may exist between the two, but the neuralgia is the result of other causes, the nasal affection being a mere coincidence.

3554 North Broad Street.

Tuberculosis and Nephritis.—Chauffard has noted nephritis in about 9 per cent. of his tuberculous patients. The kidney may be in an amyloid condition or hematuria, albuminuria and casts may indicate acute nephritis. In his study of the subject, published in the *Jour. de Méd. et de Chir. Prat.*, for Nov. 10, 1905, he mentions that in one case the symptoms of nephritis first appeared under tuberculin treatment. Albuminuria followed each injection.

CEREBRAL DECOMPRESSION.

PALLIATIVE OPERATIONS IN THE TREATMENT OF TUMORS OF THE BRAIN, BASED ON THE OBSERVATION OF FOURTEEN CASES.

WILLIAM G. SPILLER, M.D.
Professor of Neuropathology and Associate Professor of Neurology in the University of Pennsylvania.
AND
CHARLES H. FRAZIER, M.D.
Professor of Clinical Surgery in the University of Pennsylvania.
PHILADELPHIA.

(Continued from page 683.)

WHEN PALLIATIVE OPERATIONS ARE ADVISABLE.

After a careful study of these cases and of the views of the different authors, it will be seen that the weight of opinion is decidedly in favor of palliative operations. The choked disc, headache, vertigo, nausea, vomiting and, to some extent, the convulsions are all favorably influenced by this method of treatment. Relief from these distressing symptoms is by no means to be despised, even though the tumor is not removable. The relief from many of these symptoms is often permanent, i. e., during the period the patient may continue to live, and, as the growth of the tumor is not hastened by the palliative operation and may be slow, we are thankful for a means of removing the distressing symptoms of intense intracranial pressure.

My first case of palliative operation was in 1898, and the operation was performed by Dr. John B. Roberts. The marked improvement that occurred in that case and persisted at least during several years and until the patient passed from our observation convinced me of the benefit to be derived from palliative operations (Case 2 of our series).

In one of our cases (Case 10) headache was so severe that relief was demanded at once. Byrom Bramwell, as already mentioned, has attributed sudden death in some cases of brain tumor to the severity of the headache and sudden inhibition of the action of the heart. The patient to whom I refer suffered such intense pain that he could not be reasoned with and was not responsible for his acts. Occasionally, in his attacks of pain, he grabbed any one who might come within his reach and once bit his mother through the arm. The relief afforded in this case by a palliative operation has been most striking. Indeed, his relief from the previously constant pain has been so great that, as he expresses it, he is "lonesome without his headache."

In another case (Case 11) headache has been the symptom that above all others demanded treatment, and the pain in the head was associated with pain in the neck, shooting down into the upper limbs. The symptom-complex has been in large degree that of cerebellar tumor, but the pain shooting into the upper limbs has made me fear that the tumor was extending downward through the foramen magnum on the cord. Some years ago I had a case of this kind, and at the necropsy a flat tumor was found covering a part of the pons, extending into the posterior part of the fourth ventricle and growing down on the cord for several inches. In that case the development of the symptoms in the upper and lower limbs was more rapid than in the present instance, and, therefore, I feel that the tumor in the latter case may be confined to the region of the cerebellum. If so, I have no explanation for the pain in the upper limbs. The decrease of this pain, together with the decrease of the headache after the dura was opened at the second operation, gives me reason to believe that probably this pain of the limbs was indirectly caused by the cerebellar tumor. Headache and pain still occur occasionally, but the condition of the patient has been vastly improved by the removal of a piece of bone and by opening the dura over the cerebellum.

I am somewhat skeptical as regards disappearance of Jacksonian convulsions after merely opening the skull and dura if the convulsions are very frequent.

In one of my cases in which the brain was exposed by Dr. Edward Martin, and which will be reported by Dr. Martin and myself later, the tumor could not be found at the time of operation. The man was having five or six Jacksonian convulsions within an hour, and relief of intracranial pressure did not in any way check them. He died from exhaustion following the numerous convulsive seizures on the second day after the operation. After death a minute tumor was found nearly in the center of the area exposed, but a little subcortical.

In a still more recent case under my care, in which fracture of the skull and subdural hemorrhage had occurred, trephining probably prolonged life about 24 hours, but did not in any way check the Jacksonian convulsions which before the operation were as frequent as six or seven within an hour, and continued in weakened intensity but with equal frequency after the operation. Opening the skull does not seem to relieve acute irritation of the brain, but it is of benefit in chronic cases, as not rarely convulsions occurring infrequently have been rendered less severe by this procedure.

I have considered whether palliative operations can obscure focal symptoms. Bruns thinks they can not, but the subject is one that has important bearings. It is probable that a small tumor will cause more local disturbance if the general intracranial pressure is increased, not only because the local disturbance is added to the general pressure, but also because any one part of the brain is more irritable when the disturbance of the brain is general. This, however, is not sufficiently important to prevent palliative operation, and I would advise that this should be done before the general symptoms become very intense, and especially before optic neuritis has developed so far that blindness is likely to result. The apparent unanimity of opinion as regards the effect on choked discs of opening the skull makes the necessity of this operation at an early period very evident.

It is a mistake to regard palliative operations as a substitute for radical operations. The tumor should be removed whenever this is possible, and palliative measures are to be considered only when the tumor can not be located, or is too large for removal, or possibly is a glioma. Palliative operations only relieve, except in extraordinary cases such as those reported by Horsley. Codman's views that palliative operations are preferable to radical operations I can not share, and would add that the argument he offers is insufficient, viz., that the former are less dangerous in the hands of inexperienced surgeons. No surgeon who has had little experience in operating on the brain should attempt the removal of a brain tumor, and before advising the attempted removal of a brain tumor I always inquire who is to perform the operation.

The experience of Horsley as regards atrophy of tumors as a result of palliative operations seems to be unique; at least I have found no other similar cases, nor have I ever seen any such result in any of our cases. Broca and Maubrac doubted whether Horsley was correct in believing that partial ablation of a tumor may retard the growth of the rest, but Horsley has observed atrophy of a tumor following a simple opening of the skull and dura. This is a striking statement. I have never seen arrest in the growth of a tumor following the removal of a part, but several times I have seen increase of symptoms result, and I dread the partial removal of a growth, especially if it is a glioma. It has seemed to me that the congestion of the tumor and of the surrounding tissue and the greater space afforded for the growth of the tumor, after partial removal, favor the rapid growth of the remaining portion. I am almost convinced that it is better to leave a tumor untouched if only a part can be removed, especially if the growth is a glioma. The attempt, I think, should never be made to remove a glioma, and yet there seems to be no way to determine before operation that the tumor is a glioma. A patient has been under our care with the diagnosis of brain tumor and was operated on several times by Dr. Frazier. Each time as much of the tumor as could be seen was removed, and yet a return of the symptoms occurred soon after each operation, and when a necropsy was obtained the tumor (a glioma) was found to extend from the upper to the lower surface of one cerebral hemisphere.

I doubt whether it can be held that a palliative operation, by which the tumor is not partially removed, by relieving pressure, favors the growth of an intracranial tumor. Unquestionably the brain has protruded through the opening, as in the cases of Schlesinger, Frazier, and Cushing, but it seems a questionable proceeding to excise the protruding portion. The tumor has grown through the opening and on the outside of the skull (Jolly, Wiener, Putnam and others). In Jolly's case it formed an extracranial mass nearly as large as the man's head. It seems unquestionable that life was prolonged in this case by the operation, although it is doubtful if life under such circumstances is worth having. In Jolly's[33] case the clinical signs extended over a period of thirteen years. In the case that Dr. Martin and I observed, to which reference has been made, the symptoms of brain tumor had existed for eight years.

We have had some extraordinary cases in which the symptoms of brain tumor disappeared entirely or almost entirely after an opening had been made in the skull and dura. Such, for example, are the case observed by Dr. John B. Roberts and myself in 1898 and Cases 4, 5, 6, 9, 10 of our series. It may be thought that the growth of the tumor is arrested by the operation; this is possible, but doubtful. Internal hydrocephalus (meningitis serosa) or some other lesion may give the symptoms of brain tumor, and relief of intracranial pressure may cause great modification or disappearance of the symptoms. In some cases in which relief has followed palliative operations probably an incorrect diagnosis has been made; in others, the relief of pressure has permitted the tumor to grow slowly without causing many symptoms.

My views as a result of my experience and of a study of the literature are:

1. Palliative operations should be performed early in every case in which symptoms of brain tumor are pronounced and before optic neuritis has advanced far, especially where syphilis is improbable, or antisyphilitic treatment has been employed.

2. Partial removal of a tumor, especially of a glioma, is a questionable procedure.

3. Palliative operation does not cause atrophy of a brain tumor and probably does not arrest its growth; on the other hand, it probably does not hasten its growth.

4. Palliative operation is not to take the place of a radical operation when the latter can be performed without great risk to the patient.

5. In some cases the symptoms of brain tumor disappear almost entirely for a long time or permanently after a palliative operation. This result is obtained either by relief of intracranial pressure or by removal of some lesion (meningitis serosa, etc.) other than brain tumor, and yet causing the symptoms of tumor.

REMARKS BY DR. FRAZIER.

The question as to whether a palliative or radical operation is indicated may be determined by answering the question as to whether the tumor is operable or not. The operability of brain tumors has frequently been discussed and the facts and figures which have been presented to us have been based almost exclusively on the autopsy records and not on the finding at the time the operation was performed. The autopsy records may help to determine the percentage of operable tumors in so far as it reveals the nature of the tumor and may be able to fix on its point of origin. The very vascular infiltrating sarcomata should be classed with the inoperable tumors, for I believe the expectation of life and the enjoyment of that much of life which remains to the patient would be greater in the majority of cases after a palliative operation. On the other hand, the fibroma, or the somewhat defined fibrosarcoma and the gumma of limited dimensions should be classified as of the operable group. The size of the tumor as revealed at the autopsy has no practical bearing at all on the problem; the size of the tumor at the time the symptoms first made a diagnosis possible should only be considered. There are some tumors of such large proportion as to make any attempt at removal inadvisable, but, on the other hand, tumors of very small dimensions may lead to a fatal termination.

If it were possible to ascertain the point from which the tumor took its origin we should have some valuable statistics as to the operability of tumors. The farther away the tumor is from the cortex or the nearer it is to the base of the brain the more it approaches the field of inoperable growths. If the statistics are to be of much value to the surgeon they should be based on the records which are made on the operating table or at the autopsy, if the patient dies as a result of operation, only in those cases in which the patient has been brought to the surgeon comparatively early in the course of the disease. One might as well prepare a table and compile statistics as to the operability of carcinoma of the stomach based on the autopsy records of patients who died in the most advanced stages of the disease, when the lymphatic nodes far beyond the primary lesion have been invaded and the tumor is no longer confined to the stomach, but has invaded other organs adjacent to it. The question as to what percentage of tumors of the stomach may be removed must be and is being determined in the very earliest stages and on the operating table. So with tumors of the brain, the greater the number of cases brought to the surgeon in the earliest recognizable stage of the disease the sooner will we be able to say with some degree of accuracy in what percentage of cases there is a reasonable hope of being able to perform a radical operation.

There are two classes of cases in which a decompressive operation may be required. One in which there is reason to believe the tumor can not be removed in its entirety and the other in which the tumor can not be localized and yet the possible loss of vision, the intense headache and distressing vomiting almost demand the immediate adoption of some measure of relief. Cases of tumors of the cerebrum in which localization is impossible are rather the exception, although in cerebellar lesions it not infrequently happens that the tumor can not be localized.

---

[33] Jolly: Berl. klin. Wochft., July 17, 1899, p. 636.

A word or two might be said with reference to operations performed for the relief of cerebellar tumors. The anatomic relations of the structure in the suboccipital resemble in certain particulars those in the temporal region. In both the bone is covered with a well-developed musculo-aponeurotic layer, even of a greater bulk in the suboccipital than in the temporal region. For purposes of exploration it is necessary to reflect a flap of considerable size, the incision beginning at the mastoid process and, following the line of the transverse sinus to the occipital protuberance, drops in a vertical direction along the median line. And when the flap is replaced great pains should be taken to approximate carefully not only the cutaneous, but the musculo-aponeurotic layer. When the tumor can not be localized or for any other reason a radical operation is not deemed feasible a less mutilating incision will answer the purpose quite as well. A vertical incision should be made, beginning a little above the superior curved line and extending downward for a distance of three or four inches. The edges of the wound can be retracted sufficiently to afford space necessary to carry on the subsequent steps of the operation. A much more perfect approximation of the wound may be obtained as the muscles are split in the direction of their fibers and not in various angles, as is the case when a curved incision is made following the line of the sinus. This vertical incision enables one to remove the bone only from one side, but, if, for any reason, a bilateral craniectomy seems advisable, the muscle-splitting operation may be repeated on the opposite side. Such a procedure has many advantages over the conventional bilateral craniectomy in which the bone from one mastoid process to the other is removed. There is less chance of disturbance arising from traction on the pons or medulla if an intervening bridge of bone is left. In addition to this the bone in the region of the occipital region is very vascular, often riddled with vascular channels of such dimensions as to admit of a very profuse and sometimes alarming hemorrhage. The region immediately surrounding the occipital protuberance should be regarded as the dangerous zone and as such scrupulously avoided.

Failing to find the tumor, we have in certain cerebellar cases deliberately removed from one-quarter to one-third of the cerebellar hemisphere and have attributed the relief of pressure, in part at least, to this. In all our cases the operation has been confined to one side, and as yet we have not found it necessary to operate a second time for the removal of the bone on the opposite side. Even if it were conceded to be necessary to remove eventually the bone overlying both hemispheres, the operation had better be performed in two stages rather than in one; patients with cerebellar lesions are at the best not very favorable subjects for operative intervention, and preference should be given, therefore, to this procedure, which in giving the desired results will require less time and be attended with less hemorrhage and traumatism of the tissues.

First, as to those cases in which the tumor can not be localized. There are two points in the technic of the operation about which there may be some difference of opinion, namely, the area of the brain to be uncovered and the incision of the dura. The decompressive operation consists solely in the removal of a portion of the cranial vault, with or without incisions into or removal of a portion of the dura. When there is no guide as to the situation of the tumor, the operator is free to select either one of four areas: the frontal, parietal, occipital or temporal. In discussing this question several years ago, attention was called to the desirability for cosmetic reasons of avoiding both the frontal and occipital regions; there remain, therefore, but two areas from which to make the election: the parietal and the temporal. It is desirable, as Sänger suggests, to give preference to that portion of the skull beneath which may be said to exist a *silent area of the brain. This is especially* true of the right temporal region, so that, in the absence of any contraindication, this may be said to be the region of choice. Through a longitudinal incision, following the direction of the fibers of the temporal muscle, a section of bone equivalent to 6 or 8 square centimeters may be removed. One should be content to make but one opening, at least at the first sitting. This will be found in most cases to be sufficient to afford the necessary relief of pressure. If in the course of events there is evidence of a recurrence of increased tension, as shown by such symptoms as headache, vomiting or choked disc, a second opening may be made on the opposite side of the head. Such were the circumstances in one of our patients (Case 5). The headache, which had been relieved temporarily, recurred. A second opening was made on the opposite side of the head, and since that time, a period of about three years, the patient has enjoyed almost entire relief.

Speaking now only of those cases in which the tumor has been definitely localized, it is impossible to determine prior to the operation whether the tumor is one appropriate for a radical rather than a palliative operation. The duration of the disease is a guide neither to the size nor to the nature of the tumor. Malignant tumors in the brain are, many of them, surprisingly slow in their growth, and, though of many months' or years' duration, may still be in the operable stage. A very large tumor may be present with comparatively slight disturbance, or a very small one may be very serious in its consequences. A tumor of several years' duration may be no larger than a hickory nut or walnut, and yet give rise to a condition which may ultimately prove fatal.

Recently I was called by Dr. Charles K. Mills to operate on a patient who had had symptoms of a tumor for more than a year. The localizing symptoms were very vague, but all seemed to point to a lesion of the left cerebellar hemisphere. This was thoroughly explored, but with negative results, except in so far that there seemed to be a very unusual degree of tension within the cerebellar fossa. This was so suggestive of the presence of a tumor as to justify a very careful search. The results were negative. About two weeks later the patient died, and a tumor as large as a peach was found compressing the under part of the occipital lobe directly in contact with the tentorium cerebelli. Its position satisfactorily explained the existence of cerebellar symptoms. As the brain was being lifted out of the cranium at the autopsy the tumor dropped on the table. Though of large dimensions, it was clearly an operable one, and had the symptoms made it possible to localize the growth it could have been removed without any difficulty, and owing to its benign nature the operation would have resulted in a complete cure. In such a case had the operator proceeded deliberately to the performance of a decompressive operation and not attempted to explore the affected area the opportunity of saving the patient's life and of affording him permanent relief would have been thrown away.

In every instance, therefore, the operator should begin the operation with the intention, first, of attempting to expose the tumor. He should proceed as for the performance of an osteoplastic operation; the flap should be carefully mapped out and reflected and the usual exploratory measures adopted. Failing to find the growth or finding an inoperable one, the propriety of a decompressive operation is clearly indicated. He must then determine as to whether he will remove the bone of the flap, wherever this may be, or close the flap and remove the bone from the area of choice, namely, over the right temporal lobe. When, as is true in the majority of cases, the tumor is situated in the postfrontal (motor) or parietal region the bone over the temporal region may be removed through the same opening, thus avoiding the necessity of another incision. This was the procedure adopted in one of our reported cases. The patient was suffering so intensely from headache that he was operated on the day of his admission to the hospital; not waiting to make a more careful study of the case with a view toward accurately localizing the growth we proceeded at once with the intention of performing a decompressive operation. Sufficient was known of the case to lead us to believe the tumor was in the motor region. Accordingly this was laid bare and a very large vascular tumor, probably a sarcoma, was at once exposed. Deeming it to be inoperable and wishing to afford relief from the intracranial tension, only the lower half of the bone contained in the flap, which extended down to the Sylvian fissure, was removed, but through the same opening a considerable portion of the bone lying below the fissure and under the temporal muscle was also removed with Rongeur forceps. As will be seen in the record (Case 10) the headache was immediately relieved. The most important question, however, in the technic of the decompressive operation is as to whether the dura shall be incised or removed. The region from which the bone is to be removed is by comparison a matter of slight importance. To be able to answer this question one must be in a position to state from experience, first, whether the escape of cerebrospinal fluid through a dural opening is essential, and secondly, whether sufficient relief of tension may be afforded with the dura intact. As to the escape of cerebrospinal fluid there are certain observers, notably v. Bergmann, who believe that the beneficial effect of this operation is largely attributable to the escape of cerebrospinal fluid. It might be difficult, possibly, to prove or disprove this idea on theoretical grounds, but from our own experience we have not been able to note any radical difference in the results between those cases in which the dura was either left intact or if incised for exploration, was closed immediately afterwards. To the escape of a small quantity of cerebrospinal fluid through a temporary opening in the dura could scarcely be attributed the relief, which extends over a period of months or years. In so far, therefore, as the results of the operation are concerned, it makes no difference whether the opportunity for drainage was afforded by a permanent opening in the dura. In the most satisfactory of the cases under our care the dura was closed in one case, particularly, in which an exploratory dural incision was not entirely closed, the patien enjoyed no appreciable benefits from the operation.

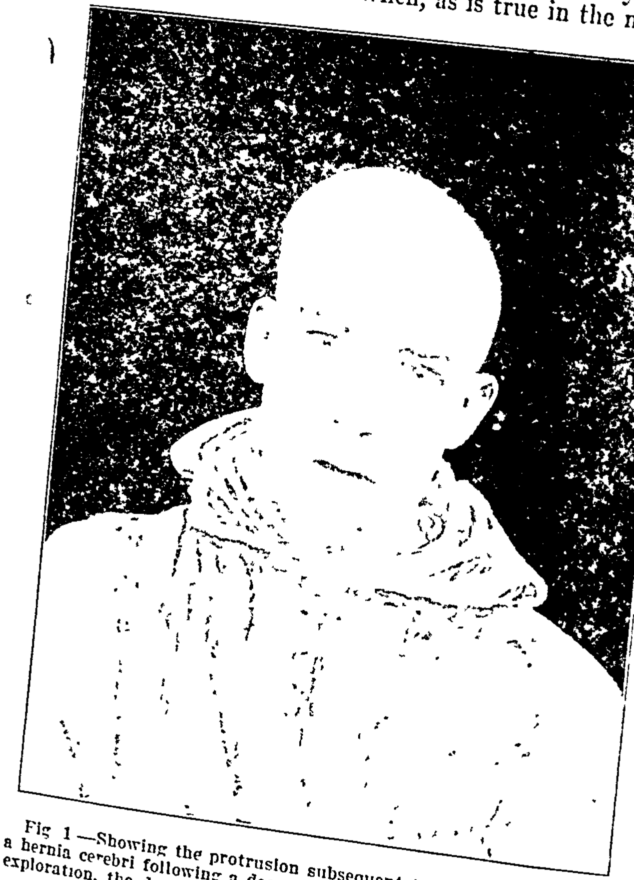

Fig 1.—Showing the protrusion subsequent to the development of a hernia cerebri following a decompressive operation, in which, after exploration, the dural wound was closed (Case 10).

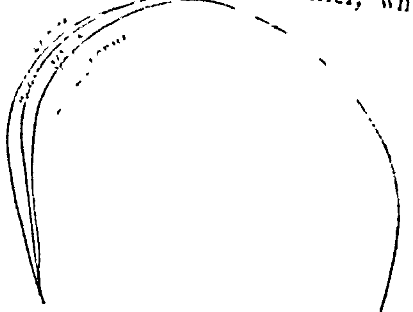

Fig. 2.—Showing the rapid development of a hernia cerebri in the decompressive operation. After the operation the dural wound was closed. The dotted line represents the normal contour on the affected side. The other lines represent the contour of the head: (1) March 30, 1906, one week after the operation, (2) April 4, 1906, twelve days after the operation, (3) April 30, 1906, five weeks after the operation (Case 10).

I think it is very generally believed (by those who have had but little experience with these operations) that the success of the operation depends on the establishment of an opening in the dura as well as in the skull. It is said that the dura is not elastic enough to stretch sufficiently when subjected to pressure. That the dura will stretch, when the overlying bone is removed sufficiently to afford adequate relief of tension, has been demonstrated in our cases over and over again. Take for example, a case which was operated on for a tumor believed to be in the occipital region. The tumor was not to be seen on or near the cortex, but there was a very much dilated right ventricle, possibly due to a tumor at the base, cutting off the intraventricular communication. If we turn to the illustration (Fig. 1), we see a genuine hernia cerebri, a hernia in which the dura as well as the scalp form the coverings. This patient has been under observation for a number of years and for the past year the hernia has not increased in size. The optic neuritis was in this case too far advanced to enable us to save the patient's vision; in other respects the patient enjoys excellent health and is now in attendance at an educational institution. A decompressive operation was not a matter of choice in this case, at least at the outset this was not contemplated. The brain bulged so through the opening that it was impossible to close the flap without removing the bone.

As an example of how rapidly the dura may stretch when subjected to excessive pressure, one of the cases of our series may be cited in which an exploratory craniotomy revealed a large and very vascular ill defined sarcoma. Its removal was out of the question, the incision in the dura was closed and a section of bone removed. Several records were made of the convexity of the head (Fig. 2) at short intervals and it is rather surprising to find how rapidly the dura had expanded to accommodate the growth. On the other hand in another case in which a tumor was exposed and found inoperable the dural incision was only partially closed. The results in this case were as compared with the other, in so far as the relief of symptoms was concerned, much less satisfactory.

Whatever else may be said either in favor of or against the removal of the dura it should be borne in mind that if the dura is removed and any complication arises in the repair of the wound it is more than likely that a fungus cerebri will develop. An accidental wound infection, the persistence of a sinus, the remains of a drainage tract may result in infection of the exposed brain tissue and that very fatal condition, a fungus cerebri. In the hands of operators, experienced in this field of surgery the danger is very slight, but it is questionable whether the removal of the dura should be resorted to as a universal practice. While in a given number of cases the results may not be so pronounced the mortality will be higher unquestionably if the dura is removed in every case. Inasmuch as the brain may herniate through the opening in the skull when the dura is left intact, there is really no necessity for removing more than the overlying bone. If the dura is disturbed at all the operator should be content with making a crucial or radiating incision in it, and in many cases it may be advisable to reserve this step of the operation until indications arise for further intervention. This course was pursued in one of our cerebellar cases in which temporary relief having been afforded the symptoms, particularly pain, recurred. A muscle-splitting incision was made, the edges of the wound retracted and a crucial incision made in the dura. The results were very gratifying and have continued so now for a period of several months.

Mortality.—Every one of the twelve patients operated on at the University Hospital, eleven by Dr. Frazier and one by Dr. Martin, recovered. The absence of any fatalities in the entire series is worthy of note. When one is debating, as to the advisability in a given case of performing a radical or palliative operation, consideration should be given to the fact that there is at least no immediate risk as to life from the decompressive operation. In the palliative measure we have an operation, which almost inevitably relieves the sources of discomfort and suffering, not only without endangering but frequently prolonging life: in the radical measure we are undertaking an operation, which has a comparatively high mortality and is only successful in a small percentage of cases in finding and removing the tumor.

Results.—The opinions expressed in the paper are based on observations in a series of fourteen cases. The first operation was performed in 1898 and the last, March 20, 1906. In but one of the entire series did the operation fail to afford the relief which would justify its performance. There was in this case some immediate improvement, but so slight as not to warrant the promise of relief which was held out to the physician and relatives of the patient. The operation was performed in March of this year, the patient was at the time almost comatose and her life was in immediate danger. At the present writing, May 25, 1906, her physician, Dr. Thomas O. Nock, writes me that the patient has been moved to the country, but her condition is little, if any, improved. All that can be said of this case is that life has been prolonged. The results in this case are a striking contrast to those following an operation performed in October, 1903. This patient probably has two lesions, one in the parietal lobe and one in the cerebellum, and before the operation suffered intensely from headache and neuralgia. When last heard from two and a half years after the operation she still enjoyed absolute relief. Perhaps the most brilliant of the series was a patient who presented the clinical symptoms of a cerebellar lesion, intense choked disc, frightful headaches, and persistent nausea, vomiting and ataxia. This patient (Case 4) was operated on two and one-half years ago and when last seen, February of the present year, he was the picture of health and was engaged in hard manual labor. Neither headache nor nausea recurred, and though he had a choked disc, so elevated that he could scarcely recognize large objects, his vision is now practically normal. Apart from the fact that he occasionally has attacks of what he calls "dizzy spells" he is to all intents perfectly well and now weighs 184 pounds.

The decompressive operation offers to the patient relief from the three cardinal symptoms of cerebral tumor, headache, nausea and vomiting, restores vision, and, if the lesion is in the cerebellar fossa, relieves ataxia and vertigo. Mention has already been made of the dangers of postponing operation once there are signs of choked disc. One of the strongest arguments in favor of the palliative operation is the opportunity to save or restore the patient's eyesight. Without exception the choked discs subsided in every instance, but unfortunately in at least three of our cases the patients remained totally and hopelessly blind because the optic neuritis was of so long duration that the nerve had undergone atrophy. The subsidence of the choked disc takes place as rapidly when the dura is left intact as when it was incised. The case, which in Dr. de Schweinitz's opinion and experience, responded most promptly to the operation was one in which the dura was not disturbed. Although the operation was performed only seven months ago the patient's vision has continued to improve. The prospects of preserving the eyesight alone would justify the operation, but no less so the opportunity of relieving headache. Our results with respect to headache have been uniformly good. There were two or three cases in which the headaches did not entirely cease, but in these there were intervals of relief and the headaches were less severe. As to the duration of the period of relief the longest in our series is between two and one-half and three years. In at least three of our cases the intensity of the pain seemed to be as great as that of a tic douloureux, and one patient had become addicted to the liberal use of morphin; yet in each one of these the relief was immediate, absolute, and permanent. In one instance the suffering was so intense that the operation was performed within a few hours of the patient's admission to the hospital, before an opportunity was afforded to determine with any degree of accuracy the location of the tumor. What has been said of the beneficial effect of the operation on the choked disc, even when the dura was left intact, may be repeated in dealing with headache. Not that the dura was not opened in some cases for exploration, but in almost every instance the dural wound was immediately closed with sutures.

Mention might be made of the fact that in two instances Nature had already begun to relieve the intracranial tension. In these cases the tumor had grown through the dura and in one instance had almost perforated the skull. In conclusion we may say that there is no form of treatment, either medical or surgical, which, in the presence of an incurable lesion, causing sometimes great discomfort, sometimes intense suffering, so uniformly affords so great and enduring a measure of relief.

SUMMARY OF CASES.*

	LOCATION OF LESION.	PERIOD SINCE OPERATION.	RESULTS
1. L....	Cerebrum....	1 year (operation was not performed but relief of pressure occurred spontaneously).	Alive and free from pain.
2. B......	Cerebellum...	7 years.......	Almost complete recovery during 2 or 3 years—present condition unknown.
3. G......	Cerebellum and Cerebrum.	2 years and 7 mo.	Alive and free from pain.
4. E....	Cerebellum..	2½ years.....	Alive and free from pain.
5. D......	Cerebellum..	2½ years.....	Alive and free from pain.
6. B......	Cerebrum...	1 year and 7 mo..	Alive and free from pain.
7. M......	Cerebellum...	8 months......	Second operation was performed, tumor found and removed.
8. K......	Cerebellum....	7 months.....	Died 7 months after operation.
9. L......	Cerebellum....	7 months.....	Alive and free from pain.
10. S......	Cerebrum....	2½ months....	Alive and free from pain.
11. F......	Cerebellum...	2½ months....	Alive and free from pain.
12. D....	Cerebellum...	2 months.....	Radical operation was p-rformed 2 months after palliative operation.
13. C.....	Cerebrum...	....	Alive but little if any relieved.
14. S......	Cerebellum...	About 3 years...	Improved—death from tumor about 3 years after palliative operation.

* A case under the care of Drs. Spiller and Martin to which reference is made in this paper, is not included in this table.

ORIGINAL OBSERVATIONS.

CASE 1.—Probably tumor of motor area. The following case is of great interest as it seems to be one in which relief of symptoms from intracranial pressure occurred by escape of cerebrospinal fluid through the cribriform plate of the ethmoid bone without operation, and it may be, therefore, regarded as a case in which relief was afforded in a manner similar to that in palliative operations.

Examination.—L. was seen by Dr. Spiller in consultation with Dr. Ernest Laplace, Aug. 13, 1904, at which time the following notes were taken: In showing the teeth the left corner of the mouth is drawn up better than the right. When drawing up each corner of the mouth separately he draws up the left better than the right. The eyelids are closed equally well on the two sides, and the resistance to any attempt to passively open the lids is as good on one side as on the other. Percussion of the scalp shows no area of tenderness. When the tongue is protruded it tends to deviate a very little towards the right. The movements of the tongue are free in all directions, and the tongue is not atrophied. The movements of the eyeballs seem to be normal in all directions, except that the movement to the left may be a trifle impaired. There is no nystagmus. The reaction of the iris to light is preserved but tardy on both sides. Convergence and accommodation can not be tested satisfactorily on account of the mental condition. The pupils are equal and regular. The masseter muscle contracts well on each side, but the left masseter contracts a little better than the right when the patient bites. He says that he feels touch more distinctly on the left side of his face. Pin prick is probably perceived in the right side of face as well as in the left, but his statements regarding sensation are not to be relied on. He understands what is said to him, although he appears dazed and has difficulty in replying, but apparently is not aphasic.

Upper limbs: The grasp of the right hand is distinctly impaired and is decidedly weaker than that of the left hand. The upper limbs are well developed and equally so. The biceps and triceps tendon reflexes on the right side are distinctly prompter than the corresponding reflexes on the left side. After a spasm the right upper and right lower limbs seemed to be almost completely paralyzed, and Dr. Laplace says that this paralysis following a spasm is only temporary.

Lower limbs: The lower limbs are well developed and there is no atrophy in any part. The patellar reflex is about normal on the left side, but exaggerated on the right side. There is no ankle clonus on either side. The Achilles tendon reflex is about normal on each side, and a trifle prompter on the right than on the left. The Babinski reflex is very pronounced on the right side; the big toe as well as the adjoining toe being drawn distinctly. The Babinski reflex is not present on the left side, the movement being flexion.

During the examination an epileptic attack occurred. It began with slight flexion of the right forearm on the arm. This movement lasted from thirty to sixty seconds before the face was involved. The right lower limb seemed to be involved before the face. Clonic movements of small extension began in the right lower limb, afterwards the movements occurred in the right upper limb. Both right upper and lower limbs were very spastic. The right side of the face was thrown into violent tonic spasm, and the lids on both sides were equally affected. There seemed to be a slight tendency of the eyeballs to turn to the right, but this was not pronounced. The lower part of the left side of the face, the left upper and lower limbs showed no convulsive movements and the left limbs were not spastic. Consciousness did not seem to be lost during the attack. Urine was not voided during the attack, but was immediately after the attack, voluntarily. After the attack the man was drowsy and passed into a light sleep lasting about five minutes.

Further Examination.—A further examination on August 14, gave the following results: Sensation for touch is more acute on the left side of the face; sensation for pain is more acute on the right side of the face; this agrees with the findings of yesterday. The grasp of the right hand is not so good as it was at the beginning of the examination yesterday. A knife or a pencil put into the right hand is distinguished without difficulty when the eyes are closed. The weakness of the right upper limb has been much greater since the attack that we saw yesterday, than at any time previously. He can barely lift the right hand from the bed. The paralysis of the right lower limbs which developed after the attack that we saw yesterday disappeared in part during the afternoon, whereas that of the right upper limb has persisted with very little change. The sensation for touch and pain seems to be more acute in the right lower limb than in the left. He seems to understand what is said to him, but has difficulty in getting words to reply and is partly motor aphasic. He yawns repeatedly, and Dr. Borsch has noticed that during the convulsive attack the eyeballs are drawn toward the right, but remain in this position only during a short part of the attack. The left pupil is larger than the right and the left recovers more slowly than the right.

Subsequent History.—The following notes were obtained from Dr. Laplace: The patient continued to improve under high doses of iodid of sodium (100 grains daily) until all symptoms of paralysis had disappeared. Headaches also disappeared, but the optic neuritis continued. The field of vision gradually lessened until total blindness ensued, January, 1905. The patient remained in this condition until May, when convulsions attended by severe headaches returned, exactly similar to those seen by Dr. Spiller in August. About forty convulsions took place in the course of the first week in May, 1905. He suffered with intense headaches and was suddenly greatly relieved of all headache and of nearly all the other symptoms on expectorating what seemed to be a certain amount of purulent material. [Dr. Laplace did not see the patient at the time of this nasal discharge]. Whether the material contained cerebrospinal fluid or whether it was pus which found its way into the nose, after burrowing its way through the cribriform plate of the ethmoid can, therefore, only be conjectured. In June and July the patient improved, but his lower extremities remained weak. This weakness of the lower extremities has increased gradually from July, 1905, until the present time. Mental hebetude gradually set in, but there has been an absolute freedom from headache, from July, 1905, until now.

Present Condition.—Complete blindness; perfect consciousness. He is thoroughly rational when aroused; otherwise quite listless. There is great weakness of lower extremities, requiring support to enable him to walk. Both arms are quite strong. Excellent appearance; good appetite and digestion; full control of bowels and bladder. Freedom from headache. Last report says that general weakness is gradually becoming more marked. Mercury and iodids have been continued. The patient and his family have opposed any surgical interference.

Case 2.—Tumor of cerebellum (?). Mrs. M. B., was admitted to the Polyclinic Hospital Dec. 31, 1898, under the care of Dr. Spiller and Dr. Robert[illegible]

History.—Patient had been married 26 years, a widow 18 years; had two children, [illegible] and 20 years old, respectively, at time of death. Emigrated to America five years ago. She had good health until previous to present trouble. Her present condition began two and one-half years ago with violent headaches in the left occipital region. Her symptoms have gradually increased in number and intensity, until at present they consist of very severe headaches in the left occipital region, great tenderness over the same region, extreme vertigo, especially when lying on the left side in bed or attempting to walk; very ataxic gait so that she staggers like a drunken person and falls to the left side or backwards.

Examination.—The patellar reflexes are absent; sensation in the legs is obtunded, and movements of the lower extremities somewhat restricted (she can not cross her legs). During the last few months she has been getting rapidly worse. A diagnosis of cerebellar tumor was made, and the patient was admitted to the wards of the Polyclinic Hospital for an exploratory operation. Urinary examination, color, amber, cloudy; reaction, acid; sp. gr. 1,020; no albumin or sugar.

Operation.—On June 4, 1899, under ether, the skull was opened by trephine and lion-jawed forceps, a hole about 1½ inches in diameter being made over the probable seat of the lesion as indicated above. The dura mater appeared normal, as did the bone removed; the dura mater was laid back, the brain exposed, the finger inserted and the surface of the brain palpated for an area of five inches or more in diameter, but no abnormality was detected. A puncture was then made into the convolutions of the brain in several directions with a grooved director to the depth of three-fourths inch without finding any lesion. The dura mater was then sutured, and the skin flap brought into place and secured. The patient made a good recovery from the anesthetic but her temperature began to rise rapidly that night, reaching 101° F. at [illegible] p. m. Infection being feared, the dressing was removed, the sutures partially withdrawn, and the wound flushed with normal salt solution. The wound was redressed at frequent intervals since, all the sutures removed.

Results.—June 30. The patient has been slowly improving since the 20th, the temperature having been practically normal. The parietal region on the operated side has almost entirely lost its peculiar tenderness to touch, and the headache occurs only occasionally, is slight and is now located in the frontal region. The patient made a complete surgical recovery, and almost all her symptoms disappeared. After two or three years she returned to Europe.

Case 3.—Tumor of the pons. Mrs. G., aged 45, was admitted to the University Hospital under the care of Dr. Charles K. Mills, October, 1903.

History.—Tumor of the pons, probably second lesion in the parietal lobe; cyst evacuated; permanent disappearance of severe headache and facial neuralgia. This patient, a woman about 45 years old, first came under the care of Dr. Mills in November, 1902. One year before coming under observation she had an attack of vertigo without unconsciousness and after this partial paralysis of the left third nerve was observed, ptosis, dilated pupil and paresis of the internal rectus being present, according to the physician then in attendance. From the history she also appeared to have had temporary paralysis of the left side of the face. She had subsequent similar attacks, some of these shortly before coming under observation. In one of the recent seizures she was found in the cellar, pacing up and down with her hands above her head, eyes dilated and apparently struggling against suffocation. She was taken upstairs and put to bed; she tried to speak, moving her jaws without uttering a sound; her face was pale, her eyes were open. At the time of the first examinations she had paresis of the left side of the face, partial ptosis, pupils equal and responsive, the superior rectus not being as active on the left side as on the right.[34]

Examination.—The patient was again examined by Dr. Mills and Dr. Spiller, Sept. 22, 1903. The left side of the face was paralyzed in the entire distribution of the seventh nerve. She complained of much pain, confined to the left side of the face and in the distribution of the fifth nerve. The masseter and temporal muscles contracted well in chewing on each side. No distinct objective disturbance of sensation on the left side of the face was made out. The left external rectus seemed to be the only external ocular muscle distinctly paretic. Astereognostic conception as tested in the right hand was almost complete.

She complained of much pain on both sides of the forehead, extending down the left side of the face to the lower border of the lower jaw. The pain did not extend below the median line of the lower jaw; it extended to the mastoid process, but not beyond this on the left side; it did not extend into the neck. She had constant pain in both temples, but it was greater in the left than in the right. All points of exit of the fifth nerve were painful to pressure; as much so on the right side as on the left. Sensation for touch and for pain on the two sides of the face seemed to be normal; she felt a touch or pin prick as well on the left side of the face as on the right. In such instances as when chewing a hard crust of bread, the left masseter contracted, but not so well as the right; in opening the mouth the lower jaw did not deviate distinctly. She complained of a sense of numbness in the left side of the face; this involved the entire distribution of the fifth nerve and extended on the left to the temple, but not far beyond the border of the hair. There was considerable improvement in the paralysis of the orbicularis palpebrarum. There was complete paralysis in the lower distribution of the left facial nerve. The right side of the face was normal. She did not have any nausea and seldom had spells of vertigo, although formerly the latter occurred frequently. She showed at times a tendency to fall backward or toward the left, but did not stagger as much as formerly; closing the eyelids did not affect the gait very distinctly. Hemiasynergia was not present on either side.

As the patient was slowly getting worse and was suffering extremely with pain in her head and face, it was finally decided to remove her to the University Hospital for the purpose of having an operation, which might at least be palliative.

---

[34] The case is fully reported as Case 6 in a paper by Dr. Charles K. Mills, on "The Diagnosis of Tumors of the Cerebellum and Cerebellopontile Angle, with Special Reference to Their Surgical Removal," New York and Phila. Med. Jour., Feb. 11 and 18, 1905.

Her pain increased until it became torturing, and for days before the operation it was necessary to keep her continuously under the effects of morphin or codein. No change of any moment occurred in her focal symptoms after the above recorded notes.

Operation.—The operation was performed by Dr. Frazier, Oct. 14, 1903, under ether anesthesia. A musculocutaneous flap together with the periosteum was reflected and an opening was made in the skull with the chisel and enlarged with Rongeur forceps. Nothing abnormal as regards pulsation nor consistency of the left lateral lobe of the cerebellum was noted. The dural flap was reflected; at one point this flap was adherent to the underlying brain. Cerebellar tissue bulged only moderately through the wound. On exploring with the index finger in the region of the cerebellopontile angle some adhesions were separated on the lateral aspect of the cerebellum. This was followed by a gush of fluid which had evidently been walled off by adhesions. After the evacuation of the cyst the bulging subsided immediately and with a brain retractor it was possible to inspect the region of the cerebellopontile angle and to demonstrate to those present at the operation, the fifth, seventh and eighth cranial nerves. It was noted on the blood pressure chart that when the dura was opened the blood pressure dropped thirty points and that on introducing gauze packing or on compressing the brain with the retractor that the blood pressure rose forty points. The patient's condition was not depressed to any considerable degree by the operation; on her return to bed the pulse was 145; respirations were 40, and blood pressure was 115.

The interesting feature of the case was the ease with which the cranial nerves were exposed after the cyst had been evacuated.

The patient reacted well after the operation and passed a fairly comfortable night. There was very profuse oozing of blood and cerebrospinal fluid, necessitating frequent reinforcement of dressing. The patient was much nauseated, vomiting curds of milk and bile-stained fluid. She complained of pain in her temples. An incomplete examination showed that sensation was present on both sides of the face and no inequality of pupils was noted. On October 15 the wound was dressed and found in good condition; the drainage was removed, there was a free flow of cerebrospinal fluid.

Subsequent History.—An examination by Dr. Mills and Dr. Spiller on October 15 resulted as follows: No cutaneous anesthesia was present on either side; not even any hypesthesia on the left. There was no great impairment of the motor division of the fifth nerve, the masseter and pterygoid muscles being tested. Complete paralysis in the muscles supplied by both the upper and lower branches of the seventh nerve was present. She was completely deaf in the left ear. Slight paralysis in the right upper extremity was noticed. Astereognosis or pseudoastereognosis was present in the right hand. Anesthesia for both touch and pain and hyperesthesia were absent. She had had no pain in the face or head since the operation and had required no anodynes.

October 19: The wound was again dressed and the stitches were removed; the wound was healed, with the exception of one angle; a small piece of gauze was inserted for drainage. The patient's general condition had been very good. Her pupils were normal.

October 24: The surgical condition was entirely satisfactory; the wound was healed, with the exception of one spot, which was rapidly granulating. The patient's general condition had rapidly improved since last noted. She was regaining strength, had been sitting up and was quite comfortable.

October 29: Patient was discharged, the surgical condition left nothing to be desired; the wound was completely healed; there was no bulging of the flap, no signs of inflammation or edema of the scalp. She had not had any pain in the head or ears; the only discomfort had been some irritation of the conjunctiva of the left eye, which was probably due to facial palsy.

Results.—When the patient was last heard from two years after the operation, the relief from headache and neuralgia continued, although, as previously stated, the pain for some time before the operation was of the most intense character. In other respects her general condition has been good. She still continues to be partially paralyzed, with astereognosis and sensory changes on the right side and still has paralysis in the distribution of the left seventh nerve. It is altogether probable that a lesion of some sort is still present; not improbably she has more than one lesion, as the symptoms point both to the pons and to the left parietal lobe. The case is especially interesting as showing how in some cases the cerebellopontile angle can be exposed and how pain and other symptoms of brain tumor are sometimes relieved even when full success is not obtained.

(*To be continued.*)

FEMORAL HERNIOTOMY.*

A. J. OCHSNER, B.S., F.R.M.S., MD.
Surgeon-in-Chief of Augustana Hospital and St. Mary's Hospital;
Professor of Clinical Surgery in the University of Illinois.
CHICAGO.

The subject of herniotomy for inguinal, umbilical and ventral hernia seems to have come to a practical conclusion by the universal acceptance of the different principles embodied in the methods in inguinal herniotomy introduced by Bassini and further developed by Andrews, Ferguson and Coley; the method of Mayo for umbilical hernia; the method of anatomic dissection and union of corresponding layers in cases of postoperative ventral hernia and hernia of the linea alba.

TREATMENT OF FEMORAL HERNIA.

It is in femoral herniæ that the methods still differ greatly. As a matter of convenience to the reader I have added a short summary of the most important ones of these various methods.

The object of this paper is to introduce into the treatment of femoral hernia a principle which has for many years been universally recognized in surgery and which has, it seems, been employed by only a few surgeons in the treatment of femoral hernia.

It is a well-known fact that it is practically impossible to keep a circular opening in any part of the body from closing spontaneously unless it be lined with a mucous or serous membrane. The anatomic relations at the femoral canal are such as to form ordinarily a definite circular opening.

LITERATURE OF THE SUBJECT.

As early as 1879 Socin[1] speaks of six of these cases which apparently were permanently cured by simply removing the hernial sac and fat and suturing the skin, thus making use of the principle which I have mentioned. Since that time I find in the literature a number of interesting articles written by Anderegg, Lesirink, Munsinger, Julliard and Biedel in which this principle was employed in a measure, but no one seems to have attributed the success of this operation in obtaining a radical cure for femoral hernia to the principle I have mentioned.

Singularly enough surgeons seem to have had perfectly satisfactory results by doing nothing further than thoroughly to dissect, ligate and remove the sac, the preperitoneal fat, and to suture the skin until the method of operating for inguinal hernia was introduced by Bassini. Subsequent literature shows that surgeons, writing on the subject of femoral hernia, reason from the conditions present in inguinal hernia, although anatomically these conditions are entirely different and, therefore, the conclusions arrived at must necessarily be faulty. As a result of this fact a number of methods have been introduced, most of them resulting in a distortion of this opening, and each of these producing a considerable number of recurrences.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

[1] Langenbeck's Arch., vol. xxiv.

AUTHOR'S METHOD.

The femoral canal is bounded anteriorly by the transversalis fascia, Poupart's ligament and the falciform process of the fascia lata; posteriorly by the iliac fascia, covering the pubic portion of the fascia lata; externally the fibrous septum separating it from the femoral vein; internally the junction of the processes of the transversalis and iliac fasciæ forming the femoral sheath lying against the outer edge of Gimbernat's ligament. The femoral opening is lined with the serous membrane comprising the hernial sac which is an outfolding of the peritoneum.

In order to change this into an unlined circular opening which must necessarily close spontaneously all that it is necessary to do is carefully to dissect out the hernial sac quite up into the peritoneal cavity beyond the inner surface of the femoral ring, ligate it high up, cut it off and permit the stump to withdraw within the peritoneal cavity. Removing all the fat contained in the femoral canal and simply closing the skin wound completes the operation for femoral hernia. This method is applicable to all simple femoral herniæ in which an actual femoral ring exists.

Occasionally there is a case in which the hernia is of traumatic origin and the opening is formed by the tearing of one edge of the ring, so that the opening is no longer regular and circular. A similar condition may also be due to a congenital deformity. Such an opening may not close spontaneously; in such cases there can be no indication for using this method. Neither is the method applicable to operations for strangulated hernia in which the femoral ring has to be cut to permit reduction.

RESULTS AND DISCUSSION.

I have used this method constantly during a period of fourteen years and am convinced that, barring unusual accidents, recurrences are out of the question if the operation is performed in this manner. I have been able to get definite reports and to examine 30 cases of femoral hernia contained in the following table. None of these operations was followed by recurrence. This number contains only a part of the patients operated, because it was not possible to get information from many of the patients of foreign birth, who do not read or write the English language and who change their residence so often that it is difficult to follow them, but there can be no doubt that the results in these cases correspond to those in which I was able to obtain information.

I have written a letter to each one of the patients on whom I operated for femoral hernia at the Augustana Hospital during the past fourteen years; 56 cases in all. Of these letters thirty-one were answered, twelve were returned through the mail, and thirteen have not been heard from.

Giving all of the answers of those that have responded will, I believe, give a fair idea of the ultimate result in these cases. I have not written to patients operated on in the other hospitals, because the number at the Augustana Hospital seemed sufficient to draw conclusions from. A greater proportion of my English-speaking patients go to this hospital than to my public clinic. I was, therefore, more certain to obtain information from the Augustana Hospital patients than from those operated in the other institutions.

It may be claimed that, if a hernial protrusion has occurred, it will occur again unless some mechanical means be employed for the closure of the femoral opening. A study of the histories of these cases shows that the original cause of the hernia can always be found in some abnormal intra-abdominal pressure of a temporary nature, or in the presence of peritoneal fat in the femoral canal. Severe gaseous distension of the intestines during childhood; whooping-cough; severe cough due to bronchitis recurring every winter; heavy lifting in young girls in the capacity of servants, before they were fully grown; pregnancy; large intra-abdominal tumors; severe sudden strains like lifting a heavy burden or being thrown from a bicycle or a moving carriage, and the presence of preperitoneal fat in the femoral canal are the most common causes. All of these immediate causes can be guarded against, and in this way a recurrence is not likely to occur.

Case 7 will serve as an excellent illustration of the permanency of the closure of the femoral ring when the operation is performed in this manner. The patient was married two years after I performed the operation for hernia. After bearing her first child she noticed a femoral hernia on the opposite side, while the canal on the side operated on remained firmly closed.

Case 8 also serves as an illustration. The patient acquired an incipient inguinal hernia during a period when she did a great deal of heavy lifting. The femoral canal operated remained perfectly closed.

Case 6 is also interesting, because it illustrates the same fact. The patient recovered fully from her herniotomy and remained so until two years later, when she suffered from an intestinal obstruction. A band extending from the mesentery of the ileum to the cecum at the base of the appendix had evidently existed for a long time, there being an indefinite history of peritonitis due to appendicitis several years before the patient came to the hospital for herniotomy. Two days before the patient entered the hospital a portion of the ileum had slipped under this band and had become strangulated. The patient was brought to the hospital with an enormously distended abdomen. She was operated on and recovered. The scar at the seat of the original hernia was stretched together with all the tissues of the abdominal wall, but this did not suffice to cause a recurrence of the hernia.

In cases in which the femoral ring has been artificially closed there is always a distortion of the circular opening unless this closure be according to the method advised by Cushing, Marcy or Kuester consisting in a circular suture which does not interfere with the arrangement of the femoral ring.

The method devised by Kocher, consisting in suturing the pectineal fascia over the opening, and the method advised by Lucus Championierre, which is very similar, are also relatively harmless. The study of the literature shows that the method of closing the opening by distorting the femoral canal will result in keeping it open in a considerable proportion of cases, some of these producing as high as 18 to 20 per cent. of recurrences. These facts seem to indicate that in this definite class of cases of femoral hernia the principle mentioned above should be employed.

PRINCIPAL FEATURES OF METHODS.

In order to sum up this subject somewhat comprehensively in the brief space in which this paper must be limited, it has seemed proper to mention the principal features of the most important methods which have been practiced in a considerable number of cases of femoral hernia.

1. Ligature and extirpation of sac: Socin, Anderegg, Leisrink, Munzinger, Julliard and Riedel.
2. Suturing of Poupart's ligament to pectineal fascia: De Garmo, Mocher, v. Frey, Berger, Czerny and Schede.
3. Two rows of sutures of Poupart's ligament to pectineal fascia by Bassini.
4. Two rows of sutures attaching falciform to pectineal fascia by Champonierre.
5. Purse string sutures: Cushing.
6. Purse string sutures and pad made by doubling sac: Curtis, MacEwen, Tricome, Coley, Reffa and Fortunat.
7. Purse string suture in several tiers: Kuester.
8. Closing femoral opening by muscular aponeurosis flap: Salzer and Dawborn.
9. Closing femoral opening by periosteal flap: Trendelenburg
10. Closing femoral opening by decalcified bone: Thiriar.
11. Closing femoral opening by ball of catgut: Schwarz.
12. Cutting through periosteum of ramus; three holes bored through bone; silk suture to Poupart's ligament: Hammersfahr.
13. MacEwen's method of making pad from sac combined with attaching Poupart's ligament to bone with mattress sutures: Nicoll.
14. And suturing Poupart's ligament to bone: Mikulicz.
15. Fastening Poupart's ligament to ramus with staple: Roux.
16. Passing a ligature through obturator foramen to tie down Poupart's ligament: Cavazzani.
17. Cutting Poupart's ligament from its moorings and sewing it to ramus: Fabricius and Delageniere.
18. Changing femoral into inguinal hernia: Ruggi.
19. Fastening conjoined tendon to ramus: Lotheisen, Codivilla and Parry.
20. Cutting entirely through Poupart's ligament just to the inside of the femoral vessels and making a triangular flap which is sutured to the periosteum of the horizontal ramus of the os pubis.

These methods may be classified in four groups:

1. Those in which the sac has been removed high up.
2. Those in which it has been utilized to form a pad.
3. Those in which the femoral canal has been left in the form of a circular opening.
4. Those in which it has been distorted either by cutting or suturing.

It seems reasonable to affirm that every method which does not contain the third of these characteristics must be considered bad from a surgical standpoint.

PROCEDURE OF DIFFERENT METHODS.

In order to make comparison convenient I have tabulated the various steps which are followed by surgeons of the greatest experience who practice the various methods which have been employed in the largest number of operations for the relief of femoral hernia.

I. SOCIN'S METHOD.

1. Skin incision a little below and parallel with Poupart's ligament.
2. Freeing of sac high up into abdominal cavity.
3. Removal of all fat and loose tissue.
4. Pulling down sac by assistant.
5. Ligating and cutting off sac high up.
6. Having stump slip into peritoneal cavity.
7. Suturing of skin incision.

II. CUSHING'S METHOD.

1. Free sac well beyond its neck, transfix it, tie it off as high as possible to avoid a funicular process.
2. Introduce a purse string suture of chromicized catgut through Poupart's ligament, the pectineal fascia and muscle, then outward through fascia lata covering femoral vessels and finally up through Poupart's ligament again coming out one-half inch from where suture was started.
3. Tie the suture and obliterate femoral canal.
4. Suture skin incision.

III. COLEY'S METHOD.

1. Thoroughly free sac well beyond neck.
2. High ligation of sac.
3. Suture is introduced through Poupart's ligament or the inner portion of the canal or crural arch, thence downward into the pectineal muscle or floor of canal, outward through fascia lata overlying the femoral vein and upward through Poupart's ligament or roof of canal, emerging about three-fourths of an inch from point of introduction.
4. On tying suture the floor of canal is brought in apposition with roof of canal and the femoral opening is obliterated.
5. Close superficial fascia with catgut or fine tendon and the skin with horse hair.

IV. CURTIS' METHOD FOR CLOSING THE CANAL AFTER THE SAC HAS BEEN REMOVED.

1. Three superimposed circular purse string sutures of catgut are introduced.
2. The first at the internal femoral opening.
3. The second one-third of an inch outside of this.
4. The third at the external surface of canal.
5. This method is not suitable for large herniæ.

V. LOTHEISSEN'S METHOD.

1. Incision parallel to Poupart's ligament and a little above same dividing fibers of external oblique and extending into external inguinal ring.
2. Expose neck of sac by entering between Poupart's ligament and the internal oblique.
3. Dislocate sac by pulling same, if small, into opening above Poupart's ligament.
4. In large hernia, dislocate the skin at the lower edge of the original incision, expose the external surface of the sac, incise sac and finally dislocate the stump of the sac in manner previously described for small hernia.
5. Suture edge of transversalis and internal oblique muscles to Cooper's ligament.
6. Suture the incisions in the aponeurosis and skin separately.

VI. NICOLL'S METHOD. (A)

1. Expose sac and clear from surrounding tissue, making the incision vertical or transverse.
2. Open sac longitudinally in middle line and clear contents.
3. Separate neck of sac for one inch around abdominal aspect of ring.
4. Bisect sac longitudinally from fundus to neck.
5. Make an aperture in one-half near the neck.
6. Interlock the halves by putting the other through one of the apertures.
7. Reduce whole sac through the femoral ring by detaching its neck from the abdominal aspect of the ring.

B—Closure of femoral ring by use of the pubic ramus.

1. Carry an incision (bone deep) from femoral vein along the pubic ramus to the region of the pubic spine.
2. Detach the periosteum to a limited extent and retract it.
3. Drill one or two holes in the bone near its upper edge one-half inch to one inch apart.
4. Pass loops of strong catgut through the apertures.
5. Divide the loop of ligature. Thread one end in a curved surgical needle and pass a mattress suture through Poupart's ligament. Repeat with second end, carrying it through Poupart's ligament at a higher level, avoiding the deep epigastric artery, and the spermatic cord above in males.
6. By means of probe withdraw both ligaments through the second drill hole in the bone.

wall bulged so much under the influence of extirpation, while the patient was on the table, that I at once decided to implant a filigree. This was done and a hernia, no doubt, was prevented. The patient died five and a half months later, however, of general carcinoma, hence, this case teaches us very little as regards ultimate results.

Case 7.—Feb. 28, 1903, I operated on a young woman, aged 22, who had had the lower right abdominal wall considerably damaged, as the result of a kick. A filigree was inserted under the shelving edge of Poupart's ligament and the aponeurosis, with the result that the patient, who had been unable to stand erect for two months before the operation, was now enabled to go about her usual vocation without discomfort. Six months later she was in perfect condition, except for a feeling of stiffness in the scar. Since that time I have been unable to get news from her.

Case 8[3].—June 22, 1903, I operated on an unmarried woman, aged 51, who had suffered for twelve years with an immense interstitial hernia. This had worked its way through the right inguinal opening, up between the aponeurosis and the internal oblique. The two structures were so attenuated, as the result of long-continued pressure, that I considered them hardly sufficient to subserve their normal functions after the removal of the sac; hence, a filigree was implanted between them with most satisfactory results. I have just heard from this patient, and learned that she has had absolutely no sign of weakness in the abdominal wall, or, in fact, no other symptom from the presence of the large mass of silver wire, since the operation, three years ago.

Case 9.—June 29, 1903, I was permitted by Dr. Deutsch, of this city, to offer some suggestions as to the treatment with a filigree of a patient on whom he operated on that date. The patient was a man, aged 36, who had been subjected to drainage for appendicitis ten years before. Within a year after the first operation a hernia had appeared in the wound, and during the succeeding nine years he had been the subject of constant abdominal colic. A large filigree was placed on the muscles which could be brought together and the aponeurosis sewed partially over this. I saw this man a year later, and there was absolutely no bulging, although, it might be added, that some of the continuous silver wire suture, which had been used in everything but the skin, was attempting to work its way to the surface. I now use catgut in sewing the various layers and have, in consequence, no more of these experiences, disagreeable to the patient and surgeon alike. I heard from this patient two years after the operation for the last time. He was, at that time, still possessed of an intact abdominal wall.

Case 10.—July 18, 1903, I implanted a filigree in Mrs. F's lower median abdominal wall for the repair of a hernia, which had resulted from a drainage operation, undertaken six months earlier for tuberculosis of the peritoneum. At present she is perfectly well and hard at work.

Case 11.—July 20, 1903, I treated, by this procedure, one of the most remarkable postoperative herniæ that I have ever seen. The patient, a woman, aged 43, had been subjected to hysterectomy six years before I saw her. She had spent six months in bed before her drained wound healed, but no sooner got up than a small bulging appeared. This gradually increased in size, until the date mentioned, when I found the low median ring, more than four inches in all diameters, and approximately round. This patient was a thin woman, with a board-like abdominal wall, which rendered it manifestly impossible to close the opening by any form of autoplasty. I implanted an immense filigree beneath the recti muscles, which were drawn out of their sheaths sufficiently to permit of them being brought together in the middle line, although the fibrous structures in front could not be approximated by any means. Two months after the operation she was in perfect physical condition, but has not been heard from since that time.[4]

Case 12.—Sept. 29, 1903, a large filigree was placed low down in the median line of Mrs. S's abdominal wall. She had been operated on fifteen years before, and had an immense hernia. She was seen recently and is in perfect condition.

Case 13.—June 6, 1905, I implanted a filigree in the lateral abdominal wall of Helen M., aged 10, on whom I had operated for purulent appendicitis six months previously. Extensive drainage had been used, and a small hernia had appeared almost as soon as she got up from bed. Since the second operation she has remained entirely cured, until the present time.

Case 14.—Oct. 13, 1905, I operated on Mrs. H., aged 52, who was afflicted by a fibromyoma of the uterus, about the size of a man's head, also by an umbilical hernia, about the size of an orange. In addition to this, there was a prolapse of the posterior vaginal wall, all three conditions being treated at *one sitting*. Through a median incision, which extended from the pubis and around one side of the umbilical ring, I excised this latter, and removed the abdominal growth. In order to close the abdomen at all I had to remove the omentum, which had lain in the hernial sac. In order to make the closure more simple, I simply placed an immense filigree beneath the edges of the thin atrophic recti muscles. It was impossible to bring these together, without too much tension, so I contented myself with merely carrying them a short distance over the ends of the wire loops, so that the filigree would remain in its bed, and over all I closed the skin. In this way it will be readily seen that I accomplished a very simple, and what has proven to be effectual, abdominal closure. In little more than two weeks this patient was up in a chair, and a few days later went home, the abdominal wound being perfectly solid.

Case 15.—Oct. 31, 1905, I implanted a filigree beneath the aponeurosis of a boy, aged 12, on whom I had operated for purulent appendicitis two weeks earlier, the wound having been left wide open. His physician removed the filigree without my knowledge a few days later.

Case 16.—Nov. 17, 1905, I implanted a filigree beneath the aponeurosis of Mr. V's abdominal wall. His appendix region had been drained three months before, but the cause of the trouble not removed. In taking out the appendix I damaged the wall to such an extent that I feared a hernia. Much pus was encountered, but, nevertheless, the contrivance healed in, with the result that he is now hard at work with a sound abdominal wall.

Case 17.—Jan. 25, 1906, a large filigree was used on Mr. K., on whom I was operating for cirrhosis of the liver. He died two days later, however, and the case has no especial instructive features.

Case 18.—Jan. 28, 1906, I implanted a filigree in Mr. D's abdominal wall, in order to forestall a hernia after a long incision for gall-bladder and appendix disease. At present he is engaged in lifting heavy weights, but, nevertheless, has remained perfectly well.

Case 19.—Feb. 19, 1906, I operated on a blacksmith for gallstone and appendix disease. Fearing that a hernia would result, in the long incision I implanted a filligree in closing the abdomen. He is now working hard at the forge every day, and is in perfect condition.

Case 20.—Feb. 27, 1906, I made a very long incision to the right of the rectus muscle in Mrs. S., the appendix was removed, and the higher structures examined. To forestall a hernia, a filigree was used in closing the wound. I saw her June 1, 1906, and know that she is in perfect condition.

Case 21.—May 18, 1906, I used a filigree in the abdominal wall of Mrs. B., aged 33. In September, 1905, her appendix had been removed, the wound was infected and an immense hernia was caused. In spite of an infection, after my operation, the filigree has healed in place as though nothing had happened.

Case 22.—May 9, 1906, I implanted in the abdominal wall of Mrs. L., a large filigree for the cure of a low median postoperative hernia. The abdomen had been opened seven years previous to this time, and an ovary removed. As soon as she got up from bed, she had a very weak feeling at the site of the incision and always wore a binder. Four years after the operation, a bulging appeared in the scar, which gradually increased in size until now it is as large as the head of a newborn infant. She felt that she had no support at that point.

---

[3] Cases 8, 10 and 11 are very fully described in the Interstate Medical Journal, 1903, No. 9.

[4] Cases 12 to 22, inclusive, as well as Case 9, are here reported for the first time.

she could not lift anything, and could not go upstairs. Her sufferings had made her a complete nervous wreck. On the date mentioned, I opened the sac, removed an immensely long appendix, and implanted a filigree beneath the muscles. Two weeks later she was up, but the next day a little pus and necrotic fat from her immensely thick abdominal wall came out at the lower end of the wound. There was no more trouble after this, however, and she is now in perfect condition.

DISCUSSION.

ON PAPERS OF DRS. OCHSNER AND BARTLETT.

Dr. A. U. Tuttle, Cambridge, Mass., said that about seven or eight years ago he read a paper on the insertion of silver wire in hernia, and that time operated on about fifteen patients. He used the wire in the treatment of ventral herniæ following appendicitis operations, also in umbilical, femoral and inguinal herniæ. Within a month of the present time he pulled out wire that had been breaking up in the patient for about six months, wire that had been put in six or seven years ago. On thinking the matter over he is satisfied that the silver wire is affected by the body juices as much as any other suture, but, perhaps, not quite so fast. After the wire had been placed in the body, whether deep or superficially, whether in a clean or in a suppurating wound, whether in a wound with primary healing or in one with secondary changes, it is only a question of a very short time when the wire becomes brittle, when it will break up and become absolutely valueless so far as holding the wound together is concerned. In regard to the question of recurrence of herniæ, the wire promotes a local irritation; sets up an increase in the connective tissue and scar formation, so that many of these cases have proved successes after the use of the wire. But the fact that silver wire produces local irritation and breaks up and comes out in fragments has been so universally noted that he thinks that after a comparatively short experience with it surgeons will see that some other suture must be used.

Dr. A. H. Ferguson, Chicago, stated that he has done operations for femoral herniæ according to various methods, finally by removing the sac and suturing Poupart's ligament and the falciform process to the pectineus muscle. But if Dr. Ochsner can show such excellent results by a still more simple process, surgeons will do well to discard all other procedures and follow his method. Dr. Ferguson has never seen a return after a radical operation for femoral hernia, either in any of his own cases or in those of others, so that the old operation probably will do as well as any other. With regard to getting at the hernia, he said that he makes his incision above Poupart's ligament parallel with it, about half an inch above it. He retracts the lower lip of the wound after exposing the ligament, then cuts through the thin fascia to Gimbernat's ligament. By this method the surgeon gets at once to the neck of the sac and with one sweep of the hand from within outward can turn out the sac and hernia on the palm of the hand. On the other hand, if he commences to dissect from the top of the hernia he will get adhesions. It will also be found that there are almost two sacs in femoral herniæ, the thin layer which covers the fat, and then the considerable layer of fat, before coming to the true sac. By going at it from above downward there will be no difficulty whatever. Every sac should always be opened. The sac should never be tied off without being opened. The other advantage of making this incision above is that the abdominal ring (external) is exposed and the surgeon can pass his finger through it and inspect the condition of the internal ring. There may be a deficiency there, which by opening up to the internal ring may be rectified and the formation of an oblique inguinal hernia prevented. Dr. Ferguson has seen several cases of oblique inguinal hernia appear on the same side that the femoral hernia was operated on.

Dr. H. M. S. Dawbarn, New York, said that he was impressed with the fact that Dr. Ochsner agrees absolutely in his teachings with other surgeons who have studied this subject carefully. For example, Czerny, Nussbaum, Sewell, Barker, Ball, MacEwen, Bassini, Halstead and others have stated time and again that unless the sac is obliterated the hernia will return. That, Dr. Dawbarn said, is the reason Heaton, the first quack to advocate the cure of rupture without the knife, failed. Heaton emptied the sac, whether it was a femoral or an inguinal hernia, and then filled it, by means of a syringe and long hypodermic needle, with glycerite of tannin, which, acting as an irritant, caused a great exudate of fibrin, "Nature's glue," partly filling the sac and obstructing a return of the hernia. Six months afterward he had the results looked up and there was 100 per cent. of relapses. Little by little, the bowel produced absorption, by pressure from above, of this plug obstructing the entrance to the sac, and finally the original trouble was reproduced. Dr. Dawbarn said that he can see no advantage in doing away with the sac though he does approve of obliterating it as a cavity. It is a mass of vital tissue and it seems wise, he said, for that reason, after dissecting it loose to carry out the MacEwen principle to make use of it, drawing it by gathering string into a solid mass well above the level of Gimbernat's ligament, to oppose by its presence the entrance of a hernia into the beginning of the femoral canal. Dr. Ferguson has used this method three times without having a relapse, although the first patient operated on has not yet passed the three-year limit. His technic is as follows: After doing away with the sac in the manner mentioned above, he dissects the loose tissue off the front wall of the rectus, leaving the bare rectus sheath. Beginning nearly at the level of the umbilicus, a strip, two or three inches wide, of the front sheath of the rectus is dissected for a sufficient distance, leaving the rectus bare. He doubles that flap down on itself, tucks it beneath Poupart's ligament, through the external ring, and sews the lower edge of that sheath with chromicized suture material to the lower edge of the femoral ring and to the pectoralis muscle and fascia. Dr. Ferguson said that it seems remarkable that surgeons generally, both in inguinal and femoral herniæ should forget that excellent principle of military tactics, namely, that if one ever expects to whip the enemy he should never forget the line of retreat. To apply that principle to hernia operations, Dr. Ferguson always makes a large semicircular or horseshoe-shaped skin incision; convex upward in inguinal hernia, convex downward in femoral, instead of the customary straight-skin cuts. These curved incisions are so placed that they surround the place where, if ever a relapse should occur and a truss life be resumed, the pad should properly rest. Consequently, the pad never would have to chafe or press on a scar, as it must do, to the patients' discomfort, if the more usual method be employed, i. e., a straight cut, in attempting radical cure over the greatest prominence of the hernia.

Dr. A. J. Ochsner stated that all the cases he reported date back at least one year, and one fourteen years. He had a most interesting experience with silver wire. About fourteen years ago while visiting Dr. Max Schede's clinic in Hamburg, he found that Dr. Schede used silver wire very freely in preventing hernia after abdominal section and in operating for the radical cure of hernia. Next Dr. Ochsner visited the Edinburgh clinic, and in speaking to Mr. John Chien was told that thirty years before a surgeon in Edinburgh had put in silver wire, and they were still taking it out. Consequently, Dr. Ochsner has not used it. He finds that with the exception of the late results for hernia in which the ring was destroyed, either by the original injury or by the operation for the reduction of strangulation, or by some foolish operation, that almost no one seems to have had a recurrence, provided, as Dr. Dawbarn says, the sac and also the peritoneal fat have been thoroughly removed.

In regard to the similarity between inguinal and femoral hernia, he directed attention to the fact that about eighteen years ago Mr. William Anderson, of St. Thomas Hospital, London, began to operate on inguinal herniæ by simply removing the entire sac, ligating it and permitting the stump to retract and suturing the skin, and when Dr. Ochsner visited his clinic seven years later, Mr. Anderson had operated on some three hundred cases without a recurrence. After that, for a considerable period of time, until Dr. Ferguson's method was published, Dr. Ochsner operated on small and medium-sized inguinal herniæ, in which there was not a congenital deformity, in that manner on one side on all double herniæ and by the Bassini method on the other side. He found that neither method was followed by an appreciable number of recurrences. Later on he made the Bassini on one side and the Ferguson on the other, and now he does the Ferguson operation altogether. But the principles mentioned must be present. Supposing the surgeon wishes to make an artificial vagina, or to keep open a rectum in which there is a stricture, he can not do it unless he lines it with mucous membrane. This principle does not always apply in umbilical hernia in the adult. In the infant where the canal is actually circular, in 97 per cent. of hernia in the adult, where the abdomen shortens umbilical hernia in the adult, where the abdomen shortens laterally, the opening is no longer circular, but becomes enlongated and the principle is abolished. These herniæ do not close by simply removing the sac.

HEREDITY AND ENVIRONMENT AS FACTORS IN THE LIFE AND DISEASES OF CHILDREN.*

C. F. WAHRER, M.D.
FORT MADISON, IOWA.

In the first chapter of Genesis and the eleventh verse it is written: "God said, Let the earth bring forth grass, the herb yielding seed, and the fruit tree yielding fruit, after his kind, whose seed is in itself upon the earth, and it was so." In the twenty-first verse: "God created great whales and every living creature that moveth, which the waters brought forth abundantly, after their kind, and every winged fowl after his kind." In the twenty-fourth verse, also: "God said, Let the earth bring forth the living creature after his kind, cattle and creeping thing and beast of the earth after his kind, and it was so." And to confirm these statements, it is reiterated, in the twenty-fifth verse that: "God made the beast of the earth after his kind, and the cattle after their kind, and every thing that creepeth upon the earth after his kind; and God saw that it was good." Thus it was a fixed law that in order to avoid confusion, every living thing, whether it be plant or animal, shall produce offspring after its own kind, thus establishing the law of heredity, and also forming at the same time, abundant proof for those who believe in the so-called bathmic evolution.

While no one, from scientist down to the most ignorant casualist, denies the matter of heredity, or that we expect offspring to be like their ancestors, yet many biologists, as well as psychologists, have devised different and even antagonistic theories to account for heredity, and its correlative factor, environment. The firmness of the belief in heredity and its influential factors in determining offspring are especially shown when there appears an apparent exception to the law, that like produces like, or what we call variation. For instance, if an auburn-haired child with blue eyes makes its appearance in a family of dark-haired, dark-eyed parents and brothers and sisters, it causes general comment, and should all questions of legitimacy be settled favorably to the suspected, inquiry will at once be made as to the matter of atavism or reversion to previous ancestors. In order, however, that one may understand, as we proceed, a few definitions may not be out of the way. Heredity is usually defined as the law that accounts for the production of offspring like the ancestors, but as we have occasionally a variation from the ancestors, we usually study heredity and variation together. Variation is usually due to some disturbing factor, which modifies the workings of the law. Weismann, a German biologist of note, held to the theory that only inherent qualities can be transmitted to offspring, acquired characteristics and habits can not be transmitted. According to him, parents are merely trustees to hand down their commingled stocks to their offspring. The effect of training and education of parents can not be inherited by the children. This differs from the saying of the late Oliver Wendell Holmes, that if you want to make a scholar out of a child its training must begin 200 years before it is born. From bad stock, according to Weismann, can come only bad offspring, and if a member of such stock, through special training and education and the result of favorable environment, should prove an exception to his family, yet his offspring will inherit but the old taint, and none of his acquired good qualities. Darwin's views are similar, primarily stated, but when we read his "Descent of Man," his theory of evolution dependent on the two great factors, sexual selection and environment, we must see that in practice, Darwin believes in the transmission of acquired, as well as of inherent, characteristics.

The English philosopher, Locke, believed that all people are endowed with the same amount of qualities or inherent characteristics, and that with the same amount of work and application all could achieve the same results in any field. The very opposite views are held by Galton, as we see in his "Faculty and Education" and his great work on "Nature and Nurture." The latter is probably nearer right than Locke. Haeckel has views similar to Darwin's, and Lamarck is diametrically opposed to Weismann, and many instances can be quoted to prove his contentions. For instance, the matter of telegony is one of them, and, while mentioning the word, I will also define it: Telegony is the reversion in children of one parent to characteristics of a former mate. For instance, a mare, having been bred to a quagga, an animal striped similarly to a zebra, later, when bred again to a horse, produced a colt with the stripes of a quagga. So, also a bitch, that was bred with a mongrel had pups characteristic in color and other qualities similar to the mongrel, yet when bred to a pure-bred animal of her own kind gave birth to a litter, some of which were marked like her former mongrel mate. Numerous examples could be mentioned which can not be gainsaid. On the other hand, we know that the rite of circumcision has been practiced among the Jews for several thousands of years, yet no Jewish boys are born without foreskins. Shepherds, who amputate the tails of all lambs, and have done so for centuries, must still repeat the process to-day, as so far no bobtailed sheep are born. But, *per contra,* Brown-Séquard, who did many bizarre things and who created artificial epilepsy in guinea-pigs, had the pleasure of seeing epilepsy develop in the offspring, even to the third generation.

Among dogs, retrievers and setters seem to have transmitted their acquired education to their offspring, as a well-born retriever will invariably practice retrieving without being taught; hence it seems the quality of retrieving, originally taught his ancestors, was in this instance transmitted to him. Weismann to the contrary, notwithstanding, Brown-Séquard's epilepsy experiments form a valid excuse now for asking the question that will interest this Section, namely, Are diseases, like certain traits, inherited, that is, transmitted from ancestor to posterity? And, if so, have these diseases always existed in this particular tribe or family, or were they first acquired and then transmitted? If the latter, how can Weismann be right, who says acquired characteristics can not be transmitted? Is there a taint of fatalism in such views that declare we can not change anything permanently, so that hereafter when a certain happy result is accomplished by environment, education and training we can not entrust it to reproduce itself, but must continually keep up the work of the same environment and training? If this were so, what is the use of the practice and study of eugenics, except as they repay us in immediate results?

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

According to the laws of heredity, if a father and a mother were in all respects exactly alike, and not taking into account theoretically their ancestors, then their offspring would exactly resemble them, and also each other. But this assumption is only to help us form the law of coefficients of heredity. Namely, if the quantity of a certain trait in the father were assumed to be one, and the same in the mother, we would expect the child to have the same trait in the same quantity, namely, one. But if one parent have this trait and the other only one-half, then we would expect the child to have only three-fourths, provided there is no prepotency existing in one parent or another in this especial trait. But—yes, but—any given person has, as far back as the tenth generation, a totality of 1,024 ancestors, including his parents, as can easily be shown by calculation. Now, all of these 1,024 have added their share of hereditary influences to his physical, mental, moral and psychical make-up, not to mention telegonic and bathmic influences, plus all the environments of Lamarck, Darwin and Haeckel. Mention of the word bathmic demands some definition. The word is from the Greek bathmos or basic; it refers to certain basic or inherent principles or characteristics existing in every individual to reproduce its own and to revert back to the reproduction of its primitive types, when not trammelled by environment or education or training. An illustration of bathmic evolution exists in the begonia and some other plants, a leaf of a begonia when planted in the ground takes root and grows and reproduces the entire plant, thus showing an inherent growth force. To illustrate more distinctly, no matter what seed is sown and under what circumstances or conditions, if it grows and reproduces at all, it will produce the same kind of organism that gave rise to the seed. By environment and education or training the horticulturist produced many varieties of apples by processes known as budding, grafting or pollenization, yet seed planted from these desirable varieties will revert to the original species, and all the acquired qualities will eventually be lost. Will this also be the case with human stock, rescued by social purity societies, prison reformers, eugenic matings of the social reformers, education of the proletariat, intermarriage of the plebeians with the patricians? If so, it will give the lie to those who claim that the continuous influx of Europeans, most of whom come from the lowest class of peasantry, is a direct benefit to the social melting pot of the earth, the United States of America, where live the greatest people on the earth—consisting of more than your 1,024 ancestors? Or have I taken for granted an aphorism whose truth is questionable and belongs not to the real truths, but the assumed ones, the *argumentum ad hominem?* If so, I have taken less for granted than many things on which rest a great number of the most ultra-scientific theories. Much of this reminds one of the contents of the witches' caldron in Macbeth:

"Round about the caldron go;
In the poisoned entrails throw
Toad that under coldest stone,
Days and nights has thirty one.
Sweltered venom sleeping got,
Boil then first i' the charmed pot;
Double, double, toil and trouble;
Fire burn and caldron bubble,
Fillet of a fenny snake,
In the caldron boil and bake;
Eye of newt, and toe of frog,
Wing of bat and tongue of dog,
Adder's fork and blind worm's sting,
Lizzard's leg and owlet's wing,
For a charm of powerful trouble,
Like a hell broth boil and bubble;
Scale of dragon, tooth of wolf,
Witches mummey, maw and gulf
Of the ravinged salt-sea shark.
Root of hemlock, digged i' the dark,
Liver of blaspheming Jew,
Gall of goat and slips of yew,
Slivered in the moon's eclipse,
Nose of Turk and Tartar's lips,
Finger of a birth-strangled babe,
Bitch delivered by a drab,
Make the gruel thick and slab,
And thereto a tiger's chaudron,
For the ingredients of our caldron,
Cook it with a baboon's blood,
Then the charm is firm and good."

This is quite a mixture and smacks of polypharmacy, yet it is a mild and harmless mess when compared to the 1,024 that come to our shores as factors in that product, called the elect of the earth—Uncle Sam's children. Is it a wonder we still have wars, murders, theft, defalcation, social evils, rebate evils, insurance swindles, and crime in high places and low, when "the butcher, the baker and the candle-stick maker," aye, far worse indeed, commingle in marriage to form the ancestors of the coming nations of the earth? Man still makes "countless thousands mourn" as in the days of the plowboy of Ayr. My ultra-scientific friends may accuse me of making a mess of scientific things and poetry yet poetry is the very spirit of truth, and of poet and scientist the former has often proved the greater seer. I might prate more wisely of the pangenesis of Darwin with his theory of gemmules which collect in the reproductive cells, and may be called "undeveloped atoms," and how they are supposed to be transmitted from parent to child, where they are said to remain in embryo undeveloped and later under suitable conditions develop and give so-called transmitted characteristics to the offspring, the theory that helped Darwin out of many rough places in formulating his theories of heredity, but, as no one yet has seen one of Dalton's atoms, so no one has seen Darwin's gemmules, or undeveloped atoms, so you see even the scientist goes begging at times for hypotheses when he is short on facts. Weismann, dissatisfied with the theory of gemmules, conceived that a germ-plasm, which was supposed by him to be a substance contained within each cell and a part of which after transmission to the offspring was never entirely used up, but transmitted to the next generation, and so on, in order to account for the continuity of the germ-plasm through ages and generations. We know cells, we know their nuclei or nucleoli, and their network and frame work, but we have never know germ-plasm, that has hitherto escaped us, though we courted it with aniline stain and acetic acid. One may as well quote poetry as such science.

The same is true of the theory of gametes and the applications of algebra, the formulæ of the calculus to establish the variant coefficients, the study of hypothetical zygotes, the elusive doctrine of Lloyd Morgan's metakinesis, the "something which is not yet consciousness, but which may develop into consciousness." All these theories and others too numerous to mention are often met with solid cold facts that are hard to harmonize. We may ask why do we continually seek to improve existing conditions, why teach or instruct, if all of it must continually be done over again, if nothing good has a continuance or abiding place, when we must fear overeducation and overtraining in one as much as undertraining in another? Will our striving ever attain some permanency? It does seem so at least! Can we improve bad stock without at the same time causing deterioration of the good stock when we practice sexual selection? Has the good and beautiful any prepotency over the bad and the ugly? Is an average better than two classes, the good and the bad? Or must we in so-called stirpiculture finally aim at the destruction of the bad by the good? Is not that a somewhat questionable procedure by the good? One is reminded, even if not forcibly of a conversation between an impertinent inquirer into the history of the ancestry of Dumas the younger. Said he: "I understand your father was a mulatto?" "Yes," answered Dumas. "And your grandfather?" Dumas answered, "He was a negro." "And his ancestor?" still probed the inquisitor. "He was an ape," said Dumas; "you see my ancestry begins where yours ends." Also another incident comes to my memory in the matter of improving our race by destroying the bad and vicious. Long ago I read an investigation into the doctrine of original sin by that great Bostonian who invented the hub around which the universe spins, the story of Elsie Venner, in which the question arose as to the right to exist, for instance, of the cats and the rats, yet the especial object in life of the cats was to destroy the rats. Did he mean that the good should destroy the bad? So far as the laws of Nature are concerned, the matter of pity has no place in her code. If an innocent babe should violate the law of gravity on a window sill of one of our skyscrapers, no good angel will interpose and intercept the falling innocent to prevent its horrid death and thus stay a tragedy in the breast of its mother. So, I think, when Nature herself is slow in making selection and survival of the fittest, man should hasten the process by the aid of environment. It may be foreign to the letter of this paper to include what I wish to say to you, but it may be useful to do so, and utility may be a reasonable excuse for any transgression of a theory. I think it would be right if, by legal enactment, the defective, the degenerate and the vicious could be so treated that procreation from such stock would be an impossibility. The researches of Dugdale remind us of the notable case of the Juke family of New York, who furnished in their progeny 1,200 people, most of whom were paupers, thieves or prostitutes, and who cost the Empire State, in trials, prisons and almshouse relief, no less than one and a quarter million dollars. How much property, misery, crime, sorrow and worry could have been saved if that old fisherman, drunkard and libertine, Juke, could have been emasculated before he set up that dynasty of crime and vice so rich in offspring, the spawn of corruption?

Our adolescent youth should have it impressed on them not to form partnerships in life with the descendants of the vicious, for it is literally true that "as we sow, so shall we reap." If parents would exercise as much of their prerogative in selecting marriage partners for their children from this standpoint as they usually do from that of worldly means and social standing, our race would be more desirable in future years than it has ever been since the disobedience of the first pair. I am sure our pseudo-reformers may mean well, but certainly do much harm, when they train the semi-idiotic and the feeble-minded and attempt the reformation of vicious criminals—the vicious youths in our reformatories and others—if they do not at the same time see to it that these hordes do not reproduce their own kind as the sands of the seashore. In doing as they now do, they only arouse their Nemesis, as Frankenstein created the monster without heart or conscience, that strangled without compunction, all that was dear to him on earth. The educated imbeciles and reformed criminals breed, if not prevented, like flies and rats. They even marry the good, if not the wise, who know not their antecedents, and thus dilute the human race with vice and degeneracy.

In the study of heredity we observe that the biologist and physicist often overlap boundaries with the psychologist, yet it is not speculating in theories that will lead us out of the realm of error into that of light so much as aiming at practical results in the study of child life that will produce the ideal boy and man, as well as the perfect girl and woman. The human embryo originates from a spermatozoön that differs very little from that of the horse, dog, ape, worm, fish or fowl, and in its history of prenatal life apparently passes through all the evolutionary forms of the various lower animals. As an analogue we may say the child in its growth and social development passes up through all the various stages of civilization from the most brutal and primitive savage to the highest forms of ideal existence. May this not by a form of atavism account for some of the usually unaccountable origins of crime, murders, thefts, the desire for tramping, sea roving, etc.? I ask, but do not answer. Despite the dictum of Weismann, that acquired characteristics are not transmissible from ancestor to offspring, the consensus of opinion of philosopher, philanthropist and statesman, of scientist and sage, is that Weismann is wrong so far as the practical results of education and training are concerned. If so, it gives pediatrists courage to go on in their good work, not only in combating and treating diseases in children, but in preventing, by proper advice and training, disease tendencies, be they diseases of the body only or those of the mind and psychic existence. These, then, are the lessons we can draw from such a study, whether we hold with Weismann that by eternal vigilance we shall obtain the prize or by holding the converse we can, by a joyous optimism, hope to see the fruits of our labors accumulate in that perfect man and woman we may see, even though only from the Pisgah of our hopes.

If Weismann be correct, if the bad by the environments of education and training can be made good, though bad stock can not be converted into good stock, then we see how grave a responsibility rests at present on every one who has to consider the problems relating to state endowments of education, the making and administering of poor laws, the conduct of charities which yearly spend immense sums. In all these problems the blind social instinct and the individual bias form strong factors in our judgment. Yet these very problems are the ones which, affecting the whole future of society, its stability and efficiency, require us, as good citizens, to understand and to obey the laws of healthy social development. The examples we have considered will not prove futile, nor its lessons worthless, even should Weismann's views, after all, be wrong. It is plain that in social problems such as I have referred to, the laws of heredity, whatever they may be, must certainly influence our judgment. The conduct of parent to child and of society to all its members can never be placed on permanent bases unless regard be paid to what science has to tell us of the fundamental problems of inheritance. The theory of evolution is not merely a passive intellectual view of Nature; it applies to man in his communities as it applies to all forms of life. It teaches us the art of living, of building up stable and great nations, and is as important to statesmen and philanthropists in council as for the scientist in his laboratory or the naturalist in the field. The laboratory experiments of a biologist may have a greater weight in practical life than all the theories of Plato, Hegel or Schleiermacher.

The scientific classification of facts, biologic or historical, the observation of their correlation and sequence, the resulting absolute as opposed to individual judgment, these are the sole means by which we can reach truth in such a vital social question as that of heredity.

1007 Fifth Street.

DISCUSSION.

Dr. F. A. Rhodes, Pittsburg, said that notable writers are diametrically opposite in their conclusions. The question will never be solved until we are able to tell what life is. Some years ago he formulated the definition that animal life (the only life with which we are intimately acquainted) is a correlation of irritable tissues. We may have in our body organs which are apparently healthy, but there may be one small organ, e. g., the pituitary body, which is diseased, and although the condition may be unknown, there is a great loss in correlation of the entire body. In regard to the investigations mentioned by Dr. Wahrer the most recent commentators are of the opinion that the results of some of the experiments are not as given by the investigator himself; that many mistakes have been made in the conclusions. The investigations in the animal kingdom at the present time are very interesting. We accept the conclusions of Burbank for the vegetable kingdom; but as in the animal kingdom the high and low forms of life are very different, so there is still a greater difference between the vegetable and animal forms of life.

That which concerns physicians most is the transmission of characteristics of physical conditions from the parent to the child, which will be for the betterment of the community. Many teach that the child who is born in the hovel of parents who are drunkards or degenerates will be a degenerate; not because of the environments, but because of the parentage. This he does not accept. While we should accept the teaching of Dr. Holmes on the preparation of a child many years in advance of its birth, yet he believes that the environment in which we live has much to do with what we ourselves or our children shall be. An illustration of this is seen in a young man who has passed from the country to the city. He has been virtuous and all the community has considered him such. When he reaches the city and becomes associated with companions of bad habits he may change completely. If the young man had the acquired characteristics which were stable and which would be permanent throughout his life, why should he, when placed in different environment, become different? Dr. Rhodes thinks children will be in accord with the environments in which they live. He studies this subject for the pleasure it gives, but is no nearer the solution at the present time than when he began, nor does he ever expect to be.

Dr. D. S. Hanson, Cleveland, Ohio, called attention to the rapid changes due to environment. For instance, it takes years and years of careful selection of seed, as in raising corn, and requires good soil to produce an ear of corn with the requisite number of seeds to cover the cob. Yet that good seed, planted successfully for a number of years, if placed in poor soil will produce a corn-cob not covered with seed. In other words, poor environment will soon destroy all that was gained by heredity. This will work out also in the animal kingdom. We see horses bred for years and a great speed developed. If such a horse is put into a plow and given the same surroundings as an ordinary horse and all training stopped, in the course of two or three generations there will be a breed incapable of development as were the former ones. In other words, environment makes rapid changes, but the changes of heredity are slow.

Dr. R. B. Gilbert, Louisville, Ky., agreed that the subject of maternal impressions is a big one. He believes that it is well established that accidents to the fetus in utero result from impressions made on the mother or even from traumatisms. He had hoped that Dr. Wahrer would make it plain just how these maternal impressions exist and what is the physiologic law governing them.

Dr. G. E. Robbins, Chillicothe, Ohio, said that he can not believe in heredity further than as a reproductive function. He can not but feel that it is environment that develops the race as we see it. If this were not true we would not be so careful of our children. As parents, said he, we are extremely careful how we rear them and how they are placed. Outside of the purely physical characteristics that may be transmitted he has no faith in heredity, but he does believe in environment.

Dr. M. E. Dunning, Newburgh, N. Y., referred to the children of the blind and deaf. Blindness is much less frequently transmitted to the offspring than deafness. More parents are born deaf than blind. A few years ago in certain statistics it was found that about 10 per cent. of the children were born blind and that the majority of parents had acquired their blindness through accident or disease. It was found that the blindness which had been acquired by the parents was transmitted so seldom to the offspring that it seemed almost an accident when it did occur.

Dr. Wahrer said his paper was certainly liable to misconceptions. He wanted to make himself clear on the point of maternal impressions. He does not believe in them in the usual understanding of the term, and they can not be substantiated except by the most careless, unscientific, hear-say evidence. The first thing many mothers ask is, "Doctor, is the child marked?" If a child is born with a deformity some one is sure to believe that the father or mother has been guilty of some sin or indiscretion. Why should the innocent one be punished? Dr. Wahrer does not believe in the idea, and the trend of medical education is away from it.

His paper was not intended to be a full treatise on heredity. It has been said that certain diseases are hereditary, but this idea is fifty years behind the time. Tuberculosis is not hereditary. We don't know whether cancer is inherited. The same thing is true of many diseases of the child. He said a study of this subject by every pediatrist would give him a different viewpoint on many things pertaining to the chld and would be to the mutual betterment of the child and its medical attendant.

A FURTHER CONTRIBUTION TO THE STUDY OF STOOLS OF STARCH-FED INFANTS.*

CHARLES GILMORE KERLEY, M.D.
Attending Physician of the New York Infant Asylum.
WILLIS C. CAMPBELL, M.D.
AND
H. N. MASON, M.D.
House Physicians of the New York Infant Asylum.
NEW YORK.

The work was undertaken with a view to adding to our information of the digestive capacity of infants for starch foods, a subject on which we have had many and varying expressions of opinion, based on clinical observations.

All the infants on whom tests were made were inmates of the New York Infant Asylum. The advantage of making such a study in institution children is obvious. when we remember that the feeding of such patients (the amount of starch given, for example) can here be kept in perfect control. Further, the test is more se-

TUBERCULOSIS OF AN ADENOMYOMA OF THE UTERUS.

WITH A PATHOLOGIC REPORT.*

J. L. ARCHAMBAULT, M.D.
COHOES, N. Y.
RICHARD M. PEARCE, M.D.
ALBANY, N. Y

That tumors in general are not subject to invasion by bacteria, other than those of the pyogenic group, is well known. The simultaneous occurrence of carcinoma and tuberculosis in an organ or tissue is occasionally reported, but the invasion of other tumors by the tubercle bacillus is very unusual. This is especially true of uterine myomata which are seldom involved in even the most extensive tuberculous infections of the adjacent mucosa. The case here reported is of interest not merely on account of the rarity of the condition, but also because of the absence of tuberculosis in the mucosa of the general uterine cavity with but a slight lesion in one tube. The tuberculosis of the myoma and that of the tube were secondary to tuberculosis of the lung, but apparently independent of one another and due to infection through the blood stream. As a fairly exhaustive review of the literature fails to reveal an analogous condition our observation appears to be worthy of record. A detailed report follows:

Clinical History.—H. E., aged 20, an only child, unmarried, was admitted to the Cohoes Hospital January 10, 1906. Her family history offers several points worthy of note. Her mother presents evidence of tabes and her father died at forty-six of a valvular lesion of the heart which formed part of the plainly luetic condition. Her grandfather, on the mother's side, had syphilis, and the grandmother succumbed to general paralysis. There is no direct tuberculous heredity.

Personal History.—The patient had measles in early childhood and showed some indications of hereditary syphilis, viz.: A slowly-healing ulcer of right leg and a nose of the saddle type.

Menstruation beginning at sixteen, has always been very scanty, irregular and tardy, with occasional amenorrhea for periods of five to six months. An epistaxis, apparently vicarious, had been frequent. Menstruation, at first painless, later became more difficult. At no time had there been leucorrhea. Dec. 14, 1904, a pelvic examination showed the uterus to be very small, of the infantile type, and lying in a moderate degree of retrodeviation, with some tenderness in the region of the left ovary.

July 30, 1904, the patient had a sudden attack of hemoptysis. A careful physical examination gave evidence of a localized adhesive pleuritis of the left apex, overlying an area of tuberculosis, involving a considerable part of the apex and extending down and outward toward the axillary line. After a sojourn at the seashore and in the mountains she was considerably improved in general health, while the physical signs had manifestly retroceded and in part entirely disappeared. The following winter (1904) was passed in the mountains and she returned in April still more improved. July 15, 1905, she had a second very slight hemoptysis, but improved rapidly, gaining by November 13 twenty-nine pounds.

Present Illness.—Abruptly, about November 21, she began to complain of soreness and pain in the hypogastric region. The pain was dull in character, intermittent, returning especially in the latter part of the day, and exaggerated by fatigue and standing. The patient had not menstruated in five months. As the pain continued unabated for a week, without any appearance of the menstrual flow, she was advised to return home. On bimanual examination, the cervix was found deviated toward the pubes and the Douglas cul-de-sac occupied by the enlarged fundus of the retroverted uterus. The fundus gave the sensation of a firm mass of about the size of a mandarin and somewhat irregular in shape, being larger on the left, and very slightly movable. The left lateral cul-de-sac was also occupied by another swelling less firm and less voluminous, having neither the fibromatous woody feeling of the main tumor nor the fluctuation of a cyst; this second enlargement seemed almost contiguous with the uterine body. The condition of the right adnexa could not be defined. These conditions were not present at the previous examination, eleven months before.

At this stage, the pulmonary condition presented a marked change. While no advancement of the disease was evident in the left apex and the corresponding axillary region, two new foci had appeared; one in the left base posteriorly and the other in the right interscapular space, close to the spinal column.

December 15, menstruation occurred and lasted five days. After a few days interruption, there was again some slight bloody discharge. This discharge kept on thereafter, more or less irregularly, until the time of operation. The pains became gradually more intense, finally requiring the daily use of some sedative for their control.

January 5, the size of the pelvic mass was considered to have increased materially. On that same date, a few tubercle bacilli with a great number of diplococci and streptococci were found in the sputum. Three previous examinations of the sputum had been negative.

Much concern was naturally entertained as to the exact nature of the uterine condition. The first diagnosis was simply one of a solid tumor, probably a fibromyoma, occupying the posterior wall of the uterus. A closer study, however, of all the evidence suggested the possibility of a tuberculous lesion of the uterus, and this possibility was carefully explained to the family.

Of course, on account of their rare occurrence, the diagnosis of any of the pelvic forms of tuberculosis is seldom made until the abdomen is opened, and even then not infrequently only after the specimen is in the hands of the pathologist. Uterine tuberculosis has no well-defined symptomatology. In the present instance, if a probable diagnosis of a tuberculous condition of the uterine growth was arrived at before operation, it is willingly conceded that we expected to find as well a similar condition of the adnexa and of the peritoneum; that is, a general abdominal tuberculosis. In holding this view, we were influenced by the existing pulmonary condition and by abdominal symptoms which predominated especially during the very last weeks. When the abdomen was opened, it was a surprise, therefore, to find that, aside from numerous and extensive adhesions of an inflammatory nature, the general as well as the pelvic peritoneum was free from tuberculosis.

Surgical Report.—January 11, laparotomy; median incision nine centimeters long. A coil of small intestine was found drawn down into the pelvis and firmly adherent close to the right uterine cornu, evidently accounting for the pain in the abdomen which had been so striking a feature. Both ovaries were fibrocystic. The uterine body, enlarged to the size of an orange, lay deeply in Douglas' cul-de-sac and was so matted up in adhesions that a subtotal hysterectomy was performed. The appendix was inspected and, being healthy, was left undisturbed.

Convalescence was uneventful, and the patient reported April 16, that she had gained ten pounds in weight and was in the best of health.

PATHOLOGIC REPORT BY DR. RICHARD M. PEARCE.

Gross Description.—The specimen consists of a uterus with its appendages. The former is exceedingly firm and almost globular in shape, measuring 17.5 cm. in circumference just below the level of the attachment of the Fallopian tubes and 19.5 cm. over fundus and cervix. The cervix protrudes beyond the globular body as a short, thin, circular canal, 0.8 cm. long and 0.4 cm. thick. Its edges are smooth, rounded and grayish-white in color. The peritoneal surfaces are covered more or less uniformly by course fibrous adhesions. On section the entire length of the uterus from cervix to fundus is 6.8 cm., the greatest thickness, antero-posteriorly, 5 cm. The body itself is 6 cm. in length. The anterior wall is normal in appearance, though slightly thickened, and measures 1.4 cm. at the mid portion of the uterine cavity. The fundus is 1.7 cm. in thickness. The posterior wall is occupied by a globular mass extending from the median line of the fundus to the internal orifice of the cervix (5.2 cm.) and laterally from the peritoneum to the uterine cavity (4 cm.). This mass is composed of firm, dense, greyish-white tissue having a whorl-like appearance and resembling the structure of myoma in a general way, but riddled everywhere by cavities varying from those miliary in size to those 0.5 cm. in diameter. From these cavities escapes a thick, yellow, more or less tenacious pus. The walls of the larger cavities, after the escape of the fluid pus, are seen to be lined by a yellow, soft granular material, suggestive of caseation. These areas extend to within two millimeters of the peritoneal surface and toward the median line approach and apparently involve the mucosa. The cervix is not involved. The uterine canal is 4.7 cm. long, 1.2 cm. of which is cervical. It is greatly narrowed and 2 cm. below the fundus is almost entirely obliterated. In or beneath the mucosa covering the lower portion of the tumor are numerous closely-set, fine, yellowish miliary areas. These do not involve the mucosa of the anterior wall nor that of the cervix.

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

The tubes and areas are atrophied. The left tube and ovary are bound to the uterus by fibrous adhesions; the right is free and has a smooth peritoneal covering. Each ovary contains a few small cysts.

Bacteriology.—Cover glass preparations of material from the cavities in the tumor, stained by methylene blue, show pus cells which take the stain well, many poorly-staining necrotic cells, and much granular detritus but no micro-organisms. Attempts to demonstrate the tubercle bacillus and the gonococcus are negative.

Agar, blood serum and hydrocele-agar tubes are sterile after 72 hours.

HISTOLOGIC DESCRIPTION.

Sections Passing Through Uterine Wall and Tumor.—The greater portion of such show a diffuse tuberculous process in a tissue composed of smooth muscle fibers and containing widely scattered tubular glands. The uterine wall proper, measured beneath the cover glass, is 3 mm. in thickness. No tubercles are present in the slightly thickened peritoneal covering, but between it and the musculature small tubercules are occasionally seen. In the muscle itself, which contains an increase of connective tissue, are a few well-developed tubercles with caseous centers. About the blood vessels are numerous lymphoid cells. The line between the normal uterine musculature and the tumor can not readily be demonstrated. The mucosa over the tumor in the upper portion of the uterus is intact but in the submucosa are irregular accumulations of lymphoid cells. At a point where the definite arrangement of the musculature ceases there is an abrupt transition to diffuse tuberculous tissue containing numerous giant cells and characterized by extensive caseation; few typical tubercles can be seen. In the midst of this are found here and there isolated areas of smooth muscle, containing tubular glands. These latter are lined for the most part by several layers of cylindrical cells, of the type found in the uterine glands, but are tortuous and show more or less irregular dilations. They are not infrequently arranged in clusters and have branching prolongations with but a single layer of epithelium. In the masses of muscle a moderate amount of connective tissue is present and also a slight infiltration of lymphoid cells. The glands are found throughout the new tissue, even at a distance of 2 cm. from the uterine wall and have no relation to those of the mucosa. There is no evidence that the channel of the tuberculous infection was along these glands.

Sections taken at three levels and passing through entire wall of apparently normal portions of uterus opposite tumor show no evidence of tuberculosis. The mucosa in each is normal. A section through the cervix shows no lesions.

A section across the entire uterine canal at a point of greatest constriction shows partial obliteration, but no tuberculosis of the mucosa. The lumen at this point contains a small plug composed of mucus, leucocytes and desquamated epithelial cells.

Right Fallopian Tube.—The mucosa is entirely destroyed. The surface is a chronic granulation tissue within its deeper layers more or less newly formed fibrous tissue. Epithelioid cells are not abundant and are very diffusely arranged. But one definite tubercle with typical giant cell is seen. An occasional oval fibrous and hyaline area is suggestive of healed tubercle, as are also a few small foci of lime salts. In the deeper layers of the muscle coat are accumulations of lymphoid cells and old blood pigment, but no tubercles.

The left Fallopian tube is atrophied, but otherwise not noteworthy. The ovaries are fibrous and contain a few small cysts but show no evidence of tuberculosis.

Careful examination of the peritoneal surfaces of the uterus, tubes and ovaries fails to reveal lesions of tuberculosis.

PATHOLOGIC DIAGNOSIS.

Tuberculosis of an adenomyoma of the uterus. Tuberculosis of right Fallopian tube. Atrophy of ovaries and Fallopian tubes. Chronic perimetritis and perisalpingitis.

REMARKS.

As already stated, we have made a search, although not exhaustive, of the medical literature for analogous cases, but have failed to find such.

Closely resembling the case here reported, however, is one observed at the gynecologic clinic of Zurich by C. Bole (du Locle).[1] A summary of this case reads as follows:

History.—Woman, aged 50; heredo-tuberculosis; menstruation at thirteen; leucorrhea. Patient married twice, no children. Dysmenorrhea and loss of strength.

Present State.—Uterus anteflexed, movable, slightly tender on pressure and about the size of a child's head in volume.

Diagnosis.—*Uterine myoma.*

Laparotomy.—Total hysterectomy after Freund's method. The tumor, when extirpated, is twice as large as one's fist. The macroscopic and microscopic examination showed that it was a rare case of myoma associated with an ascending uterotubal tuberculosis. The vaginal mucosa was not involved, and the etiology could not be determined.

This case, however, is not identical with the one here reported. The tumor is intramural, but the tuberculosis is spoken of as an ascending uterotubal infection, and the myoma as associated with it. From this it may be inferred that the mucosa alone was involved in the tuberculous process. This inference also finds support in the statement that the histologic researches bore only on "the superficial portions, in a state of necrosis." Thus, it would appear from these comparisons that our case might, indeed, deserve to be considered as unique.

Kelly[2] states that "tuberculosis of the endometrium is exceedingly rare as complication in the large myomatous uterus." He has met but one case and in this the disease had extended out into both tubes.

A last point not to be overlooked is the mode of infection or of transmission to the uterine parenchyma.

As regards the pathogenesis of the local lesions in our case, it seems very plausible that the adenomyoma constituted the primary lesion and that the tuberculous infection occurred secondarily. But how did this infection take place? How in this particular case was it transmitted from the lungs?

From the clinical history and from the findings at the time of the operation it seems fair to believe that the propagation of the lesions to the uterine tissue took place through the blood current, and in a similar manner to the only tube involved.

---

[2] "Operative Gynecology," vol. ii, p. 381.

Infection by means of the blood stream seems to be well supported by the conclusions of M. Schakoff,[3] which may be given as follows:

Genital tuberculosis in women is generally secondary to a florid or latent tuberculosis of the lungs or of the peribronchial lymph nodes, less frequently to an intestinal tuberculosis. The genital tuberculosis is generally propagated by the blood stream, except in the case of vaginal tuberculosis, which may proceed from inoculation by contact.

Tuberculous peritonitis occurs frequently during the evolution of a genital tuberculosis, especially after a tuberculous salpingitis. Any portion of the genital tract may be affected; the tube is involved more frequently, the vagina less often. These inoculations take place by the blood stream; therefrom the uterus or the ovary may become infected by contiguity. Generally the uterus is infected by descending contagion; it may, however, be involved in the first place. A pre-existing disease and the puerperal state may act as predisposing causes. The uterine cervix is rarely the seat of tuberculosis. The tuberculosis of the ovary is almost always consecutive to a tuberculosis of the Fallopian tube, of the peritoneum, or of the rectum; the propagation occurs by contiguity or by way of adhesions. Independent foci may, however, be found in the ovary without any lesions of the surrounding structures; in such cases these foci have been set up by the blood stream.

In the above conclusions, the two points of practical bearing on our case are: 1. Genital tuberculosis in women is generally secondary to pulmonary tuberculosis. 2. In tuberculosis of the uterus or of the ovary, when the tuberculous lesions are found as independent foci without lesions of the surrounding structures, the inoculation has taken place by the blood current. That the latter would appear to be the case is indicated by the absence of tuberculosis in the mucosa, not only of the uterine cavity generally, but also in that covering the tumor itself. It is possible that alterations in the blood supply of the tumor caused a condition of degeneration or necrosis constituting a *locus minoris resistentiæ* and a point of selection for tubercle bacilli reaching these areas through the blood stream.

DISCUSSION.

Dr. Henry A. Christian, Boston, thought that in a case of this kind without close study two interpretations might be given of such a tumor mass. First, that the mass is a proliferative form of tuberculosis, such as frequently occurs in the lymphoid tissues; the other is that it is a definite tumor infiltrated by tubercle bacilli. The presence of glands in this tumor gives weight to the latter interpretation. It seems almost impossible to have these glands in the mass without its being a true tumor formation; moreover, their presence may have been necessary for the development of the tubercle bacillus. Ordinarily, in a fibromyoma there are not the conditions in its dense structure for the good growth of the organisms. In this case there is a loose cellular tissue about the glands which is more favorable for the growth of bacilli. The presence of the glands is of importance in simplifying a diagnosis and determining the character of growth.

[3] "Contributions to the Knowledge of Tuberculosis of the Female Genital Organs," Gynäk. Helvet., 1904, p. 139.

Is Boric Acid Ointment Sterile?—On the basis of 125 examinations of boric acid ointment Nyman (*Farmaceutiskt Notisblad*, abst. in *Apotheker-Zeitung*, No. 59, 1906), comes to the conclusion that boric acid ointment with a minimum content of 10 per cent. of boric acid is sterile, but that the sterility of ointments containing less of the acid can not be assumed.

OCULAR INJURIES FROM FOREIGN BODIES,

WITH REPORT OF 420 CASES.*

WILLIAM M. SWEET, M.D.
PHILADELPHIA.

In the following paper are recorded the results of a study of 318 cases of ocular injury from foreign bodies in which Roentgen ray examination was made, the report supplementing a previous study made in 1901 of 102 similar cases. A tabulated statement of the 420 cases is given below.

For purposes of study the vitreous chamber is divided into three sections, the region of the equator including that portion 3mm. in front of, and 3mm. back of, the equatorial diameter; the ciliary region that portion in front of, and the posterior region, that portion back of, the outlined zone of the equator.

Position of body.	First series.	Present series.
In the eyelid	1	2
In the lens	3	14
In iris, or posterior chamber	1	4
In the ciliary region	24	27
Near the equator	21	69
Posterior part of eyeball	12	46
In the orbit	3	11
No body found by x-rays	37	145
Total	102	318

Of the total number of injuries, 356 were caused by particles of iron and steel, 23 by copper, 25 by bullets or small shot, and 16 by glass, stone or coal. In 17 cases the body was situated in the eyelid or orbit, in none of which did the eyeball on the corresponding side escape injury. In one the injury to the lid was complicated by an incised wound of the cornea, prolapse of the iris, and traumatic cataract, all of which must have been made by a second body which did not lodge in the eyeball, or by a blow from one of the workman's tools.

The right eye was injured in 178 cases and the left eye in 242 cases. The relatively greater frequency of injury of the left eye is probably due to the position taken by right-handed workmen in handling their tools and in chipping or hammering metal.

The majority of patients were referred to me for x-ray localization from the Wills Hospital, the Jefferson Hospital, the University Hospital and the Pennsylvania Hospital, and I am under obligations to the surgeons connected with these institutions who operated on the cases for assistance in recording the ultimate result in each case. Many of the patients have remained under observation since operation. Some have returned periodically for examination, others have been visited at their place of business or at their homes, so that the present condition of their eyes has been determined. In others it has been impossible to learn the late result because of removal from their previous homes, and adoption of other methods of livelihood.

In the first series of cases, which includes injuries seen from 1897 to 1901, there were 65 cases in which a foreign body was located in the eyeball or surrounding tissues. Since this published report, three eyeballs were removed, two for iridocyclitis a few months later, and one because of recurring hemorrhage into the interior of the eyeball four years after extraction of the steel. The ultimate result in these 65 cases, so far as data could be obtained, together with the results in the 318 cases of the present series, is as follows:

EYEBALLS ENUCLEATED:	First series.	Present series.
Extraction not attempted or failed	14	19
Extraction successful; enucleated later.	8	26

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906

	First series.	Present series.
EYEBALLS ENUCLEATED:		
No operation attempted	7	13
Bodies in the orbit or eyelid	4	9
Extraction failed	2	6
EXTRACTION SUCCESSFUL:		
Vision, between 6/6 and 6/12	7	20
Vision, between 6/15 and 6/60	4	13
Fingers or hand movements	0	7
Good light projection	9	27
Light perception	6	21
No light perception, eye normal size	0	6
Eyeball shrunken	4	6
No bodies shown by the x-rays	37	145
Total	102	318

The first series of cases covers a period during which the small Hirschberg magnet, operated by fluid batteries, was practically the only instrument available, and insertion of the magnet point into the vitreous was necessary in nearly every case. Notwithstanding the added traumatism of the magnet, the visual acuity in these cases has been retained up to the present time.

In the present series of cases, magnets with greater attractive power have been used, and, although a few of the surgeons have adhered to the method of introducing an elongated tip into the vitreous, most of the operators apply the large, short tip of the magnet at the wound of entrance or at an incision made in the sclera, only entering the smaller point when the magnet at the scleral opening fails to withdraw the body.

In a few instances the metal was removed by the Haab magnet, but in the majority of cases the Sweet magnet operated on the 110-volt lightning circuit was used. Bodies situated in the lens or in the posterior chamber were extracted by way of the anterior chamber, and this plan was followed in four of the bodies located in the vitreous chamber, but the operation of choice has been to withdraw the body through the wound of entrance when still open, or through a meridional incision in the sclera made close to the indicated position of the body, the point of selection being between the external and inferior recti muscles.

In most cases of recent injury the larger magnets have sufficient power to attract the metal without entering the point into the vitreous, and it is only when the body is embedded into the choroid or sclera that insertion of the magnet becomes necessary. It is true that good vision has resulted in spite of the entrance of the magnet point deeply into the vitreous, but experience has demonstrated that this procedure increases the traumatism and contributes to ultimate shrinking of the ball or to iridocyclitis.

Cases not seen until weeks or months after injury must be dealt with according to the site of the metal and the symptoms from which the patient suffers. The x-ray localization will often assist the operator in judging of the possible difficulty in removing the metal. Bodies situated above the horizontal plane of the globe or posteriorly in the vitreous chamber are usually caught in the coats of the eye, and in a few days or weeks become firmly bound by inflammatory exudation which resists extraction even with the magnet point brought close to the indicated location. Bodies at the bottom of the vitreous, in the neighborhood of the ciliary body or equator, usually drop into this region after penetrating the anterior segment of the globe, and, not having penetrated the retina or choroid, are more readily secured, even after remaining in the eyeball for a considerable period.

In old cases that will presumably offer difficulties in the extraction of the metal, operative interference may be postponed so long as the eye is quiet. The patient, however, must understand the necessity of promptly seeking advice should inflammatory symptoms arise. If the injured eyeball is irritable, or sympathetic irritation exists, an attempt should be made at once to extract the metal, and in the event of failure the ball should be enucleated without delay.

EYEBALLS SAVED.

In the first series of cases, extraction was successful and the eyeballs were saved in 30 cases, 7 with vision better than 6/12, 4 between 6/15 and 6/60; 9 with good light projection; 6 with light perception, and 4 with slightly shrunken eyeballs. In the present series, extraction was successful in 100 cases, with vision better than 6/12 in 20, between 6/15 and 6/60 in 13, counting fingers or hand movements in 7, good light projection in 27, light perception in 21, no light perception in 6, and eyeballs shrunken in 6. In the total 63 cases with light projection or light perception removal of the cataract would ensure serviceable vision in many of the patients.

A summary of the 106 cases of the present series is given in Table 1. The details of the first series of cases studied have been previously published,* and are therefore not given here.

An analysis of the visual results in the patients that have been under observation for a period of years, in which a scleral incision was made in the extraction of the metal, indicates that retinal detachment following this method of procedure must be of rare occurrence. In not one of the cases in the tabular statement in which the media permit a study of the region of the incision made in the ocular structures has detachment of the retina occurred, although in many of the patients a sufficient period has elapsed to exclude further retinal or choroidal changes. The continued irritation and exudative inflammation of a long retained foreign body in the coats of the eye is probably a more potent factor in causing detachment of the retina than a small, clean cut of the sclera and the adjacent retina and choroid.

In several of the tabulated cases retinal detachment was present prior to extraction of the metal, and in many eyeballs with only light perception the retina is likewise detached, but it is difficult to say whether the presence of the foreign body or the insertion of the magnet point in the removal of the body was the primary cause of the detachment.

EYEBALLS LOST.

In the first series of cases. 22 eyeballs were lost, in 7 of which the injury was by non-magnetic bodies. In 9 cases extraction was not attempted; 3 cases were injuries from steel, and 6 from copper or small shot. In 5 cases extraction failed, and on enucleation, the metal in the eyeball was found firmly embedded in new fibrous tissue. In 8 cases the body was successfully removed, but enucleation was required in 5 cases because of iridocyclitis, in 2 cases from recurring hemorrhages into the vitreous, and one from panophthalmitis.

In the present series, 45 eyeballs were lost, in 35 of which the injury was from iron or steel, 6 from shot and 4 from copper. In 12 cases no attempt was made to extract the metal; in 7 cases extraction failed, while in 26 the body was successfully removed. In 8, evidences of panophthalmitis was present at the time of examination, and in 2 the ball was immediately removed, in 5 on the following day, and in 1 on the ninth day; in the other 18, the magnet point was inserted into the vitreous in nearly every instance, increasing thereby the traumatism, and probably in a large measure contributing to the iridocyclitis that compelled ultimate enucleation. In a number of these cases the body had remained in the eyeball a sufficient time to render the saving of the globe problematical, even in the event of successful extraction. The period between injury and operation in the 18 cases was three days in 3 cases; four days in 1; five days in 2; seven days in 1; fourteen days in 1; sixteen days in 1; twenty-four days in 1; four weeks in 2; five weeks in 2; and the remaining 4 cases, six months, eight months, eighteen months and thirteen years, respectively.

* Copper. † Shot.

A further cause contributing to the loss of the eyeball in a number of the cases was the severe traumatism at the time of injury, the large size of the metal almost immediately destroying the usefulness of the eye. The dimensions of the body in nine cases were as follows: Case 113, 5x4 mm.; case 153, 8x5 mm.; case 154, 12x6 mm.; case 207, 14x1 mm.; case 298, 7x3 mm.; case 313, 10x7 mm.; case 364, 9x2 mm.; and case 406, 12x9 mm.

The summary of the 45 cases in which enucleation was required is given in Table 2.

The comparatively few cases of panophthalmitis, indicate the resisting power of the vitreous to infection. To some extent disinfection of the body may occur as it passes through the coats of the eye into the interior. Even if the instances of late iridocyclitis are considered as types of infection, the percentage of loss from this cause is small in comparison with the large number of cases of injury. Two causes act to produce loss of the ball from iridocyclitis, the formation of a fibrinous exudate about the foreign body that complicates the extraction by the insertion of the point of the magnet once or more into the vitreous, or the original traumatism is so severe that the eye can not recover.

NO BODIES IN THE EYEBALL.

An unusual large proportion of the total number of injuries was shown by the radiographs to have no foreign body in the eyeball or orbit. In each, the diagnosis of the presence of a foreign substance within the ball was probable from the character of the work on which the individual was engaged, the nature of the injury, and the condition of the eyeball or the reduction in vision.

Of the 145 cases embraced in the present series, 30 were seen within 24 hours of injury, 32 between the second and fourth days, 42 between the fifth day and the end of the second week, 27 between one month and nine months, and 14 over one year. In 49 cases cataract existed, 28 in patients examined during the first week after the injury and 21 after this period; in 5 cases hemorrhage into the anterior chamber was associated with a wound of the cornea or limbus; in 8 cases extensive posterior synechia was present, with opacities on the anterior lens capsule; in 13 recent injuries there was hemorrhage or opacities in the vitreous; while in 20 cases of old injury vitreous opacities prevented a view of the eyeground.

Of the total number of injured eyes showing no foreign body, 124 were caused by iron and steel, 10 by copper from premature mining explosions, 7 by glass or stone, and 4 by small shot.

ORBITAL CASES AND CASES UPON WHICH NO OPERATION WAS MADE.

In 20 cases of ocular injury in which the radiographs showed the presence of a foreign body in the eyeball or surrounding structures, no operation on the eyeball was performed, and so far as could be learned, none of these eyes has been removed. Cases in which no operation was performed, but the eyeball enucleated, are included in another part of this report. Of the 20 cases, 4 were foreign bodies in the lens, two of steel and one of copper; 8 were in the vitreous, six of steel and two of small shot; and 8 were in the orbit, three bullets or small shot, four steel, and one stone. In three patients the eyeballs were shrunken and enucleation was advised, but refused.

There is a more general recognition on the part of the attending physicians who are usually first consulted in these ocular injuries from foreign bodies, of the importance of an early diagnosis. A higher percentage of successful extraction, with preservation of vision, would be secured if every case of ocular injury with reduction of visual acuity was subjected to the x-ray examination within a few hours after injury, and the foreign body immediately extracted, should one be shown to have penetrated into the eyeball. Such a course would most largely contribute to the saving of the eyeball and the preservation of some sight, although with the same methods of operation, the same precautions in surgical technic and the same promptness in diagnosis and in extraction, the result in one case may be a shrunken, tender eyeball, that must ultimately be removed, while in another case full acuity of vision will be secured.

SUMMARY.

Total number of injuries from foreign bodies, 420; foreign bodies located in the eyeball, 221; in the orbit, 14; in the eyelid, 3; no bodies shown by the Roentgen rays, 182. Injuries by iron and steel numbered 356; copper, 23; bullets or small shot, 25; and glass, stone, or coal, 16.

In the 221 cases in which the foreign body was located in the eyeball, extraction was successful in 164 cases, with subsequent enucleation in 34; extraction failed in 18 cases, with enucleation in 10, and no attempt was made to remove the body in 39 cases, with enucleation in 19. Although 34 eyes were enucleated after successful extraction of the metal, the majority of these eyes were lost as a result of the original injury and not from the operation. Thus, in 9, evidence of panophthalmitis was present at the time the case was first seen, and in 9 others the large size of the metal inflicting the injury left little hope of saving the eye, while many of the others were old injuries, in which the body was only secured after numerous insertions of the magnet into the vitreous.

The results of operation on the eyeballs containing foreign bodies were: Vision better than 6/12 in 27; between 6/15 and 6/60 in 17; counting fingers or recognition of hand movements, 7; light projection, 36, and light perception 27, with a certainty of increased vision in many of these cases on the removal of the cataract; no light perception, but eyeball of normal size, 6; shrunken eyeball, 10.

CONCLUSIONS.

1. Radiographic examination should be made in every case of ocular injury from a foreign body in which lowered visual acuity is a result of the accident.
2. Extraction of a foreign body through a small meridional incision in the sclera, the magnet point not introduced into the vitreous, causes no greater traumatism than follows drawing the metal through the vitreous into the anterior chamber.
3. Retinal detachment is not a logical result of a scleral incision for the extraction of a body from the vitreous chamber. The exudation associated with a long-retained foreign body is probably a more frequent cause of detachment.
4. Introduction of the magnet point into the vitreous increases the traumatism to the eyeball, encourages retinal detachment and often leads to shrinking of the eyeball and to iridocyclitis.
5. Bodies located above the horizontal plane of the globe or at the posterior part of the vitreous chamber usually present greater difficulties in extraction, owing to the early formation of a fibrous exudate around the imbedded metal, than bodies at the bottom of the vitreous near the equator, to which position they fall after penetration.

DISCUSSION.

Dr. Howard F. Hansell, Philadelphia, declared that the literature of more than 10 years ago, or before the utilization of the *x*-rays and the elaboration of the methods of diagnosis and treatment that have developed since that time, is of historical interest only. The recent extensive literature discusses the subject variously and brings into prominence two opposed opinions—first, that localization is superfluous and second, that localization is essential for scientific therapeutics. The believers in non-localization proceed without delay to the extraction with the Haab or other large magnet, usually through the anterior section of the eye, with consummate skill, drawing the metal around the crystalline lens through the pupil. Those who favor the median-sized magnets prefer localization and subsequent extraction through the cornea of bodies situated in the lens or anterior to it and through an opening in the sclera for those posterior to the lens. Dr. Hansell believes in the latter method for the majority of cases, but he believes also that localization is not indispensable to the successful management of the minority, even when the body can not be seen. For example, a linear wound in the cornea, an opacification in a hitherto clear lens and a blot in the field of vision will indicate that the body is in the vitreous, in the coats of the eye or in the orbit. The precise location in the vitreous is of little moment, for, if it is possible of extraction, the body may be drawn through an opening in the sclera made at any convenient place, usually between the external and inferior rectus. Again, *x*-ray localization presents two drawbacks. Our success in localization, thanks to Dr. Sweet's labors, has made us dependent on the diagnosis of the radiograph and too little stress has been laid on the chances of error. A statement only of the possible inaccuracies may be sufficient to avoid mischief. Dr. Hansell has previously called attention, he said, to the chance of error due to a swollen lens or to a grossly myopic or hyperopic eye, in calculating the exact position of a foreign body. In other words, the comparison of a healthy emmetropic eye with one in which the lens is wounded or which is appreciably larger or smaller, is not accurate. He also said that the foreign body may be so small that the shadow on the radiograph escapes the closest scrutiny. This also is exceptional, having occurred but once in my experience. Dr. Hansell said that it is quite within the limits of good practice to omit the radiographic examination in some cases of ocular injury from a foreign body in which lowered acuity of vision is a result of the accident. The apparatus may not be available and valuable time is lost and danger to the eye incurred by a railroad journey of some hours. The immediate application of the magnet to the unclosed wound will avoid the delay and danger, and will determine both the diagnosis and the cure. He said that it would seem to be a simple matter for a patient to know that the wounded eye needs treatment or that the sound eye is suffering from some of the symptoms of sympathetic inflammation, and yet experience does not prove the assumption. A few weeks ago he removed an eye that had been injured 14 years before and had been blind for almost all that time. There was an uncertain history of the entrance of a foreign body but the retention of that foreign body had not been suspected. The sound eye was beginning to be sympathetically affected. After enucleation a minute fragment of steel was found in the ciliary region, too small to cast a shadow on a skilfully taken radiograph. Dr. Hansell believes that incurably blind eyes, particularly those blinded through injury, should be removed. They are and ever will be useless and are always a menace to the sound eye. Patients who lose their eyes from injury are not as a rule well informed and are not to be trusted to know when treatment is required. This opinion is applicable whether the injury be caused by a substance too large to be retained in the ball or one which may or may not be capable of attraction by the magnet. In cases of recent injuries he agrees with Haab that it is safer to allow non-magnetizable particles to remain in the eye unless they are known to be easily accessible, than to probe the vitreous with forceps or other instruments. He called attention to the excellent results of the operation of extraction as recorded by Sweet, and said that it must be remembered that in comparing these statistics with those of injuries and operation in other parts of the body, recovery is often hopeless from the moment of the accident. Of the 420 cases, the total of both series, the radiograph showed the absence of any foreign body in 182, leaving 232 only to be considered. Of these, 51 recovered vision ranging from 6/6 to counting fingers, 22 per cent. Without extraction of the body it is probable that 99 per cent. would have been lost. Statistics such as these of methods of diagnosis and operation in a comparatively new procedure and concerning which there is a diversity of opinion, are of the greatest value in stimulating other workers to renewed efforts for the saving of the eyes which, without scientific experimentation, would be given up as lost.

Dr. J. Ranly, Cincinnati, said that having been impressed with the occasional failures in the attempts to remove foreign bodies he constructed a stronger magnet, hoping to overcome this difficulty. It is so built that the blunt-pointed pole pieces can be brought within one and one-half inches and turned at any angle desired so that a slanting direction of the magnetic influence can be obtained. By removing the anterior portion of the Haab tip and attaching a flexible extension arm which can be moved with ease in any direction all the advantages of the hand magnet are obtained plus more power. After the foreign body is brought into the anterior chamber he makes a corneal incision at the most favorable place so as to avoid prolapse of the iris, then applies the magnet tip above the foreign body over the cornea and moves it in the direction of the incision. The incision he considers of great importance and thinks that a place should be selected not near the foreign body as we are compelled to do with the weak magnet, but it should be situated at the most distant part, since the foreign body can be moved anywhere in the anterior chamber without causing any injury. The danger of a small corneal incision being much less than that of a scleral incision is a sufficient reason for removing the foreign body in that way, first bringing it into the anterior chamber by means of the giant magnet.

Dr. W. F. Coleman, Chicago, mentioned one point in regard to the magnet that served him excellently and demonstrated his remarks with a diagram on the blackboard. The ordinary Haab magnet has such a large point that in a case some years ago he could not enter it and devised an arrangement with a ball and socket joint, which permits of movement of separate tips in any direction. In removing the foreign body he can not see the reasons for Haab's directions to remove it through the anterior chamber, thus running the risk of producing cataract. In a former statement Dr. Kipp referred to a case in which he had been able to extract a foreign body by reversing the poles. Dr. Coleman does not believe that will practically occur. If one takes a short piece of steel, lays it on a paper and takes a hand magnet and puts one pole toward it and then reverses quickly, either pole will attract the particle and neither pole will repel it.

Dr. Frank C. Todd, Minneapolis, said that the slight improvement in results which Dr. Sweet's statistics show over those of Haab, seem to him to result from more careful localization of the foreign body by radiographs, which he understands Dr. Haab has not employed. Since hearing Dr. Haab's paper on his work in the extraction of foreign bodies, Dr. Todd has practiced the method and has been surprised at the ease and success with which it could be carried out. It seems to him to have certain advantages, in many cases, over removal through the sclera, particularly when the body can not be observed. By Haab's method, it is brought to the edge of the lens, back of the iris (after which, the entire process can be observed), then coaxed to the pupil and out into the anterior chamber, to be removed at the corneal margin through an incision. Dr. Todd has secured the effect brought about by Dr. Coleman's attachment by using a steel instrument, one end touching the magnet, the other entering the lips of the wound. It may thus be moved about readily, and the foreign body will become attracted to it.

Dr. S. D. Risley, Philadelphia, stated that he is at one with Dr. Sweet in his conclusions. So far as injuries which result from foreign bodies are concerned Dr. Risley thinks we should distinctly differentiate between those caused by the entrance of the foreign body itself, by its presence in the vitreous chamber, and those which may be caused by efforts for its extraction. In the first place it should be borne in mind that the foreign body is not always clean and to extract it by a method which makes a new path through the vitreous increases the liability of infection, and is not, therefore, a scientific procedure. It should be extracted by the shortest possible path, and after localization we know just which path to choose. The incision should be made with a sharp knife and the conical tip of the magnet should be placed against the lip of the wound and patiently held there until the foreign body presents itself. He regards this as the ideal method since it causes a minimum of traumatism at the hands of the surgeon. We should hold as an aphorism that it is bad surgery to introduce instruments of any kind into the vitreous when it can be avoided. To insert the long strip of magnet deeply into the vitreous is, to his mind, an illogical and certainly a most dangerous procedure, and one which in his experience in the majority of instances has been unnecessary. He mentioned a case seen in consultation in which the foreign body had been located by Dr. Sweet. The surgeon asked Dr. Risley's advice as to the locality for incision and he suggested a point nearest the foreign body as shown by the localization chart, but he disagreed and made the incision on the opposite side of the globe and inserted a long tip so that the foreign body was pulled entirely across the vitreous chamber. As to the question of polarity, Dr. Risley has seen a foreign body, a sliver of bright metal 8 mm. in length, reverse itself, end for end, and then approach the magnet, emerging at the original wound of entrance. It was in the anterior segment of the eye and could be readily seen through the widely dilated pupil.

Dr. Wm. H. Wilder, Chicago, emphasized the matter of radiographs in these cases. He thinks that many of us are prone, as soon as we suspect the presence of a foreign body in the eye, to apply the magnet at once, and it may be in some cases with disastrous results. It is often used in this way to make a diagnosis. He feels sure from experience that this should not be done, and he has seen one or two striking instances in which he was unable to demonstrate the presence of a foreign body. In one case there was a piece of steel as large as the end of a lead pencil. It had penetrated with a remarkably small wound and had pierced the posterior coat of the eye and lodged against the optic nerve. The patient experienced no sensation whatever when the most powerful current was applied. The eye subsequently had to be enucleated. He thinks that in many cases if the surgeons were more careful to obtain a radiograph, and especially by means of some apparatus for localizing the foreign body, there would be less injury to the eye than by at once applying the magnet. He agreed with Dr. Risley that the shortest course that we can have the foreign body pass through is preferable to the method of removing it through the anterior chamber.

Dr. Edward Jackson, Denver, recently saw a case with Dr. Stevens, in which a splinter of steel was seen hanging back of the lens, with a wound of entrance showing in the cornea, anterior capsule and posterior capsule. We extracted the splinter with the Johnson magnet through the sclera and the lens has cleared up completely.

Dr. T. J. McCoy, Los Angeles, stated that during the last ten years he has had charge of five different roads and has had to do with a great many foreign body cases. Because of unprincipled attorneys they have to be extremely careful in the location of foreign bodies and have instituted a system; first the *x*-ray is used; second, the written consent of the patient for removing the body is obtained, because disastrous results may sometimes occur. Without that they will not have anything to do with it. Experience points to the fact that the best results are obtained by making the incision nearest to the location of the foreign body. In one case the accident was due to the explosion of a cartridge at twenty feet distant and the patient was struck in the eye. It was impossible to tell whether the foreign body was there because of the hemorrhage. It was located with the *x*-ray and was removed. In another case in the last three weeks a miner was struck with a stone; it was located with the *x*-ray and removed. In dealing with these cases among these miners, mostly foreigners, the physician must be very careful to secure consent first before operating.

Dr. William M. Sweet, Philadelphia, believes that there is a class of old injuries in which the metal may be allowed to remain so long as it is not causing any symptoms, and the patient understands the importance of prompt treatment in the event of trouble. Patients frequently seek advice for the removal of a traumatic cataract, and are surprised to learn after *x*-ray examination that a foreign body is in the eyeball. An attempt may be made to remove the body with the magnet point placed at the lips of a small incision in the sclera, and in the event of failure the body may be allowed to remain if all reaction following the operation subsides. Numerous insertions of the magnet point into the vitreous in the hope of securing the body from the firm exudate in which it is possibly imbedded may ultimately succeed in removing the metal. Dr. Sweet would rather leave a piece of steel in the eyeball than a piece of copper. He thinks that the tabular statement of the eyeballs least worthy of study, as it indicates in each instance the cause of failure to preserve the globe. A certain number of eyes had to be removed because of the severe traumatism from a large-sized foreign body, but the larger proportion were lost from delay on the part of the attending physician in recognizing the possibility of a foreign body having lodged in the ball. If these cases were seen earlier the results of operation would be more favorable. In compiling the summary of the tabular statements no figures were presented of the results achieved by other operators, since it is practically impossible to draw satisfactory conclusions in comparing groups of cases which involve so many factors that affect the ultimate saving of the eyeball or the preservation of sight. Apart from the fact that the cases summarized cover the experience of many different operators, some of whom adhere to the plan of inserting the magnet point into the vitreous in recent cases, the ultimate results of operation are further influenced by the size of the foreign body, its position in the eye, and time elapsing between the injury and extraction. If we compare the 182 cases in this report in which extraction was attempted with the 165 cases reported by Haab, Dr. Sweet said, we have the following: Extraction successful, Haab, 141 cases, or 85.5 per cent.; this report, 164 cases, or 90.1 per cent. Extraction failed, Haab, 24 cases, or 14.5 per cent.; this report, 18 cases, or 9.9 per cent. Eyeballs requiring enucleation, including only cases in which extraction was attempted, and was successful or failed, Haab, 39 eyes, or 23.5 per cent.; this report, 44 eyes, or 24.2 per cent. Good sight, Haab, 51 cases, or 30.9 per cent.; this report, 44 cases, or 24.2 per cent. Light perception or projection, which could probably be improved to serviceable vision in a large proportion of the cases by the removal of the existing cataract, Haab, 20 cases, or 12.1 per cent.; this report, 70 cases, or 38.4 per cent. Sightless eyeballs, Haab, 19, or 11.5 per cent.; this report, 16 cases, or 8.8 per cent. Extraction failed, but eyeballs not removed, Haab, 12 cases, or 7.5 per cent.; this report, 8 cases, or 4.4 per cent. In de Schweinitz's report of 26 cases, the results were as follows: Good sight, 10 cases, or 38 per cent.; eyeballs lost, 8, or 30.8 per cent.; eyeballs saved, which probably could have been improved by subsequent operation, 6, or 23 per cent.; eyeballs saved, but ball somewhat shrunken, 2 cases, or 7.7 per cent.

Clinical Notes, New Instruments, Etc.

A NEW SHIELD FOR USE IN NOSE AND THROAT EXAMINATIONS.

I. J. KERR, B.S., M.D.
Physician to the Tuberculosis Dispensary.
CLEVELAND, OHIO.

One of the greatest dangers to the physician handling patients suffering from tuberculosis lies in having masses of muco-pus thrown into his face by the patient sneezing or coughing while the nose, pharynx or larynx is being examined. The greatest danger exists in the public clinics where the patients are not over-particular to restrain a desire to cough while being examined. These patients are also apt to have very irritable throats which render them more liable to cough while the tongue depressor or the laryngoscope is being used.

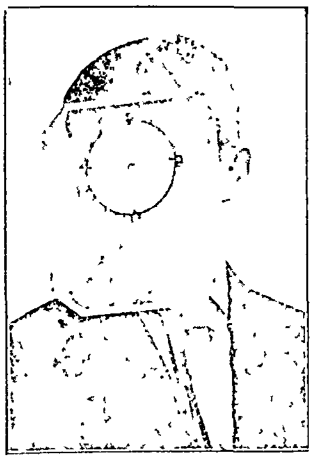
So far as I know, a glass in metal frame suspended on a movable arm between the face of the patient and the face of the physician is the only device which has been used to protect the physician up to this time. This is certainly a great protection, but it has many obvious disadvantages, among which are the clouding of the glass by the breath of the patient and physician, and its size and position.

During a recent visit to the New York Municipal Clinic for Tuberculosis, Dr. Waters, chief of the clinic, showed me a celluloid shield which had been made for him, but which was not satisfactory and did not seem to me practical. It was simply a sheet of celluloid, with temples similar to those used on spectacles, fastened to the sides, the idea being to wear this shield under the head mirror.

DESCRIPTION OF SHIELD.

I have thought out and had made for me the following device which seems to me satisfactory in most particulars:

It is of celluloid, which, of course, is inflammable if held too close to a flame or very hot surface. I have protected it partly from this by binding its surface with thin strips of aluminum. In this form if it is not held within four inches of the top of the gas or oil lamp, directly over the flame, the danger is very slight, as I have proved by tests. Even if the shield is brought directly in contact with the metal condenser on the lamp after it has been burning for some time it does not ignite. If by chance it does ignite it does not burn rapidly enough to expose the wearer to great danger.



I have considered the possibility of making a shield of mica, but in sheets large enough to make such a shield it would be very expensive. Then, too, it is very easily cracked or splintered, so that it would not be durable. If expense were no object this shield could be made of mica in the same way I have my celluloid shield.

The shield is 7x9 inches and is attached to the posterior surface of the head mirror by four clamps fastened to its surface. A hole is made in the shield in the proper place for the shank of the mirror, and this can be at either side of the center line, according to which side of the light the patient is placed. If the examiner wears glasses a hole may be cut in the shield corresponding to the aperture of the head mirror. The shield may be easily detached from the mirror to be cleaned or disinfected in formalin, or in case the mirror is to be used without the shield.

With good sharp illumination I have no trouble in being able to make the ordinary nose and throat examination while using this shield.

Keenan Building.

A CASE OF POISONING FROM OPIUM OR MORPHIN IN A 7-WEEKS-OLD BABY.

EDWIN OLANDER, M.D.
ST. PAUL, MINN.

On July 6, 1906, I was hastily summoned to see a seven-weeks-old baby whom the mother said was getting blue in the face at times, as if in the last throes of death.

When looking at the child I observed that when it became cyanosed the cyanosis was not caused by a typical convulsion, but rather by embarrassment of respiration. I immediately examined the eyes and found typical pin-point pupils, not reacting to the light. I questioned the mother as to any medicine which had been given, and she brought me a bottle of Jadaway's Elixir for Infants, manufactured by the C. W. Wilson company. The directions read:

A child less than 2 weeks	5- 8 M.
A child 2 to 4 weeks	8-12 M.
A child 4 to 8 weeks	12-18 M.
A child 2 to 4 months	20-30 M.

The mother stated that she had purchased the bottle at a neighboring drugstore, and on the evening of July 5 had given the child five drops for colic. I believe that she had really given this small dose. I knew that I was dealing with a case of opium or morphin poisoning, and told the mother so.

Emetics, high enemas, massage and stimulants were administered, and on the morning of July 7 the child was fully recovered.

The pure food bill which has passed Congress, from a physician's point of view, is many years behind time. We must now see that it is strictly enforced, as it will aid in the prevention of such cases of poisoning as this.

Here a child had been give one-third the dose which the bottle stated could be given and yet suffered severe poisoning from this dangerous preparation.

A CASE OF INTESTINAL OBSTRUCTION.*

FRANK S. HOUGH, M.D.
SIBLEY, IOWA.

I have made no extensive examination of the literature of intestinal obstruction, but from the nature of this case I believe that it is a rare one.

History.—Mrs. A., aged 30, married one year, was operated on by me two years ago for destructive disease of the appendages. Nine years ago she suffered from pus tubes and general pelvic inflammation. Both ovaries were mere sacs filled with soft necrotic material, and all the other evidences of long-continued inflammations were present. She was a physical wreck. For about a year she suffered severely from the artificially-induced menopause; after that she commenced to put on flesh and became, apparently, the picture of health.

Present Illness.—On the evening of May 9, she partook liberally of sauerkraut. Se returned home and retired with a feeling of well being. Some hours later, after midnight, her husband saw that she seemed ill, as she was groaning and rolling about though still asleep. He aroused her and she said that she had great abdominal pain; the abdomen was found to be swollen. Soon she commenced to vomit and the pain increased in severity. I was summoned some time later and was loth to diagnose obstruction because one classical symptom, the element of shock (as registered by pulse, temperature and skin) was wanting. The patient vomited incessantly for sixteen hours.

Treatment.—I made many unsuccessful attempts to pass a long colon tube, but at last my efforts were rewarded by such an immense discharge of gas and feces that I thought, and told the family, that things were now all right. The pain and vomiting stopped for an hour and then the same symptoms returned and I found that I had only emptied the colon and that the small intestine was still enormously distended. I suspected volvulus near the lower end of the cecum.

Operation.—An eight-inch incision was made through the right rectus and was followed by evisceration of practically all the ileum, which was greatly distended and cyanotic. Not having a Paul's tube or other similar contrivance, multiple incisions were made in the bowel which allowed of evacuation of contents. The emptied bowel was sutured and returned. The cecum was located and an effort was made to elevate it and the adjacent ileum but it could not be done. The constriction could be felt, however, and a distended black loop of bowel was fished up. A white glistening cord was apparently tied around it. This cord was round, about three inches in length and the size of one's little finger, resembling somewhat a thick fibrous appendix. The herniated loop could not be extricated until the cord was exsected. By the application of hot wet compresses the strangulated bowel changed in color from black to rosy red, and no portion of the bowel was removed as its mesentery seemed all right and it had resumed a contracted natural appearance.

---

* Abbreviated from a paper read before the Upper Des Moines Medical Association, Spirit Lake, Iowa, July 11, 1906.

Result.—The patient did not vomit after the operation and on the second day she commenced to pass large quantities of liquid feces. The abdomen flattened and became normally tympanitic. Her recovery was rapid. She required cascara and epsom salts almost daily for two or three weeks before the bowels regained a normal condition.

The condition was of the nature of an intra-abdominal strangulated hernia. This cord was attached at one end to the bowel wall furthest from the mesenteric attachment, and to the adjoining mesentery near the bowel, so that a ring existed whose circumference was cord, bowel and mesentery. The diameter of this ring was one and one-half inches. This old adhesion was about six inches proximal to ileocecal valve, and on inspection another one almost identical in appearance was found a few inches proximal to that which was exsected to prevent subsequent trouble. These bands were undoubtedly the vestiges of her peritoneal inflammations years ago, and were there when I operated on her pelvic organs two years ago, but no search was made in this region at that time. She might have carried them around with her for years without suffering any inconvenience had not an unaccustomed dinner, and perhaps more especially the sauerkraut, excited violent peristalsis, and the ileum being thrown into violent action became strangulated by this band.

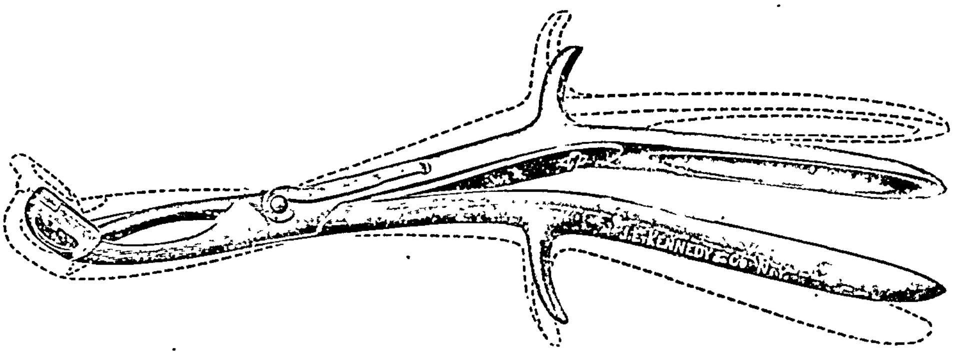
Strangulated herniæ through the omentum, diaphragm and mesentery are not very rare. Adhesions often bind the bowels together and cause obstruction, and adhesions do the same by crossing the intestine. Such a case as this seems to me to be very rare. Had operation been delayed longer her chances would have been small, and my delay was due to the fact that I was unable to reconcile an unaffected pulse of 75, warm extremities, natural skin and no apparent depreciation of strength with volvulus or other form of obstruction, in spite of the distension, pain and vomiting.

A NEW ADENATOME.

GEORGE B. McAULIFFE, M.D.
Chief of Clinic and Clinical Instructor, Department of Otology,
Cornell University Medical College, Chief of Clinic, Aural
Department, New York Polyclinic Hospital.
NEW YORK.

While many surgeons maintain that forceps are unnecessary in adenoidectomy, experience has proved to others that a radical operation is much better accomplished by the use of the forceps, followed by the curette. The majority of forceps are modifications of the Lowenberg model, two spoons, grasping the mass between them. No instrument has hitherto been designed (except Concannon's) that prevents the wounding of the anterior boundaries of the pharynx and of the uvula. While the majority of operators are expert enough to avoid these accidents, nevertheless these mishaps are reported often enough to merit attention to this defect in the design of the instruments. Some operators, like Myles, use the finger to prevent the inclusion of the uvula. That the probability of accident hampers the freedom and quickness of the adenoidectomy is without doubt.

The instrument shown here meets the difficulty by hinging the cutting blades where they come in contact with the anterior boundaries of the epipharynx. The uvula can not get in the way and the attention of the operator can be centered on the adenoids, which fall easily in the jaws of the instrument. Besides, the economy of motion in the opening of the blades to their full sweep makes the manipulation of the instrument very easy. The addition of the obstetric prongs enables forward pressure to be made against the adenoids. Despite the multiplicity of parts the instrument is sterilizable; and the separability of the cutting blades from the handles permits of the use of different sizes of cutting blades on the same handles. I am indebted to Mr. J. Kennedy for many practical suggestions.



AN IMPROVISED POCKET CASE FOR EYE DROPPERS.

J. G. PARSONS, M.D.
BROOKINGS, S. D.

Feeling the inconvenience of carrying a bag to hold dropper bottles when making a visit to eye patients, I have improvised a pocket case which will, in a measure, serve the oculist as the tablet case does the general practician. As may be seen in the picture, the case is an aluminum hypodermic case. Four of the tablet vials are used to hold solutions. Two droppers, one amber for atropin, are made by drawing out tablet vials in an alcohol flame. In the mouths of the droppers are fitted rubber bulbs from vaccine tubes, the perforations being closed with bits of rubber. The syringe hole carries a tube which may be used for another solution, or, as shown in the cut, an open tube, plugged in the middle with a cork, may be used to hold two kinds of powder.

SATURDAY, SEPTEMBER 8, 1906.

THE AMERICAN MEDICAL ASSOCIATION: ITS FRIENDS AND ITS ENEMIES.

During the first fifty-five years of its existence, lack of effective organization and of sufficient funds prevented the American Medical Association from undertaking to carry out certain objects that from time to time have been emphasized as advisable for the good of the profession. During this time the work of the Association along these lines was limited to the occasional adoption of resolutions, or to the appointment of committees which could do little but make recommendations. In 1902 the feeling which had been growing that a closer and more effective organization was required resulted in the adjustment of the principles of medical organization to present-day conditions, and in a most remarkable organization movement on the part of an awakening profession. At the same time, careful, conservative management on the part of the Board of Trustees, combined with the application of modern business methods to the conduct of the affairs of the Association, finally resulted in the accumulation of a surplus.

Thus with the necessary means and a compact organization the Association, for the first time in its history, was in a position to take up work that heretofore had been out of the question. For instance, the House of Delegates in the last three years has established the Council on Pharmacy and Chemistry and the Council on Medical Education, and has ordered the compilation and publication of a national medical directory. The objects of these three movements are the same: the accumulation of facts and the publication of the truth regarding matters of direct interest and importance to the medical profession. The Council on Pharmacy and Chemistry was created to investigate proprietary preparations and to inform the profession regarding them; the Council on Medical Education was established to coöperate with licensing boards and with medical colleges for the purpose of improving medical education and of bringing about practical methods of reciprocity in licensure, in other words, to advance the cause of a higher standard of medical education; the directory was established with the object of presenting to the profession the official facts regarding every practicing physician.

These objects are altruistic in every sense of the word and are for the betterment of conditions affecting both the medical profession and the public at large. In this work the Association should receive the support of every honest man, whether layman or physician. And yet opposition has arisen! Who are the men and what are the interests that are seeking by indirect methods, by misrepresentation and personal attack, to obstruct and to nullify the work of the Association? In the answer to this question will be found the key to the entire matter.

This opposition, apparently widespread and diverse. will, when analyzed, be found to come from four different sources. These are: 1. The Proprietary Association of America, which, it will be remembered, circulated most malicious and libelous attacks on the American Medical Association, sending these to the newspapers all over the country, and which in other ways did all it could to create a public sentiment against the Association. This was because the American Medical Association lent its influence and support to the efforts that were being made to enlighten the public regarding the frauds that were being perpetrated on it by the "patent medicine" men. 2. The so-called "ethical" proprietary medicine men, whose products or methods would not bear investigation. 3. Those privately-owned medical journals which were more or less dependent on the income received from the above. 4. The firm owning and publishing a medical directory.

It was foreseen from the beginning that the most bitter and persistent opposition would come from those who would least relish a comparison of the claims they made in their advertising and the goods they sold; whose stock in trade consisted of alluring advertisements rather than of meritorious products. These expectations have been realized.

It is in some respects an amusing matter to note the marked change that has taken place in the views of certain commercial interests regarding the Association. So long as it was without capital, so long as its activities were necessarily limited to the passing of resolutions, so long as the Association did nothing—so long was it lauded and praised as a great and beneficent body. But mark the sudden change. No sooner were active measures inaugurated for the betterment of existing conditions and for the correction of evils long known and recognized than the Association was assailed, its officers were attacked and their motives impugned for doing exactly what they had been instructed to do by those representing the profession. Caricature, ridicule, invective, misrepresentation, half statements and distortions of the truth have all been utilized to check the work of the Association.

Failing in these attacks from without, however, and finding the Association at Boston more harmonious and more united than ever before, an attempt is now being made to disrupt the Association and to nullify its work by creating dissensions and suspicion in the Association itself. In this attempt to create discord have been engaged not only the elements and influences noted above, but also, to their shame be it said, medical journals which for years have claimed a place in the very van of medical progress, and whose standing was such as to warrant the belief that they would not stoop to print deliberate and malicious falsehoods. One of these journals, whose columns in the past have been kept filled by contributions from the most prominent members of the body which is now being attacked, whose publishers for years have derived large revenues from our profession, has seen fit to follow the lead of the weak, subsidized journals in this attempt to disrupt an organization of those who have contributed to the success of the publication and who have made the fortunes of its owners possible. Incidentally it may be noted that among all the slurs and attacks made on the Association and its officers there have been no definite, tangible accusations, no specific statements, but, on the contrary, insinuations, vague generalizations and indefinite hints of alleged or assumed mismanagement.

To these attacks so far no reply has been made, because the officers have continually been assured by the friends of the organization that the source and the animus of these assaults were fully apparent to all, and because they deemed the work in which the Association was engaged of too great importance to waste time or effort in defense. Possibly no explanations are needed now, but when members of the Association of years' standing, men like Dr. Carstens, whose sincerity, honesty and loyalty to the Association are beyond suspicion, write letters and ask questions which show plainly that they have been misled and have accepted as facts the vague statements and indefinite insinuations made by those who are interested in creating dissatisfaction and suspicion, and when falsehoods and malicious misrepresentations are being circulated by journals hitherto of good repute and standing, then it is evident that the time has come to state some plain truths in order that the members of the profession may know the facts. Neither the Association nor any of its officers have anything to fear from full and complete publicity of all facts relating to the work that is being done or to any of the affairs of the Association. As a matter of fact, full and complete publicity has always been made regarding everything concerning the Association. No board of directors has ever presented to its stockholders a more complete or detailed account of affairs than has the Board of Trustees to the members of the American Medical Association relative to the affairs of the Association. There has been nothing to conceal in the past; there is nothing to conceal now. The more the profession and the public know of the work of the Association the more heartily will they support it.

We propose, therefore, to discuss in the immediate future the various phases of the work of the Association and the reasons for the opposition to it. Part of this matter we shall discuss editorially, but the greater portion, however, will be found under the head of "Pharmacology," a department of The Journal which has contained the matter that has stirred up nine-tenths of the opposition, as our readers well know.

HEART BLOCK.

One of the most interesting discussions during the recent meeting of the British Medical Association at Toronto was that on heart block in the Section on Medicine. The term is probably not familiar to most ordinary practitioners of medicine, and the idea which it conveys has really only been introduced into medical science in the last few years. The idea intended by the term is that heart impulses which begin in the auricle do not succeed in passing over into the ventricle because they are blocked in their progress. This "heart block" is due to the fact that a particular bundle of muscle fibers through which the heart impulses are conducted has its function interfered with by some pathologic or traumatic condition and thus prevents the passage of these impulses. The result, as expressed in the picturesque language of Professor Gibson, of Edinburgh, is a divorce between the auricles and the ventricles. Instead of following the auricular beat immediately, the ventricular beat is distinctly delayed or is even suppressed entirely for one or more impulses, the consequence being a distinct irregularity in the heart rhythm.

The ideas which underlie this new theory, for it must not be forgotten that it is not as yet beyond the theoretic stage in spite of the gradual accumulation of considerable pathologic evidence in its favor, began to be evolved about a decade ago. Professor His, the distinguished German anatomist, described a special bundle of muscle fibers which, having their origin in the auricle, pass through the auriculoventricular junction to be distributed in the ventricular septum and in the walls of the ventricles. This bundle of muscle is quite distinct from the neighboring muscular fibers. It has an enveloping connective tissue sheath of its own and is surrounded by a network of nerve fibrils. Its color is even a little different from that of the adjoining tissues, being somewhat paler, and, indeed, this pallor has sometimes been considered to indicate a pathologic condition in the heart muscle and has been pointed out as an evidence of degeneration.

As stated by Professor Aschoff, of Berne, the old idea that heart weakness is the result of a general inflammatory disturbance of the heart muscle, a myocarditis, consequent on the presence of infectious elements in the circulation, has not been sustained by the more careful investigations of recent years. Certain infectious diseases always produce inflammatory changes in the myocardium. These are the exception, however, rather than the rule. Diphtheria nearly always produces such changes. Rheumatism, meaning, of course, acute rheumatic arthritis, has a specific effect on the heart muscle and gives rise to certain small pathologic lesions situated just below the endocardium which resemble miliary tubercles in many respects. Beyond these two infections, however, none of this class of diseases has a serious effect on the heart. The old idea of a generalized inflammatory disturbance of the heart muscle is not substantiated. The examination of over 100 hearts with all the modern staining methods and careful microscopical technic has failed to show it. It has been found, however, that in cases where heart failure threatened or actually occurred the essential affection is limited to this bundle of muscle fibers which, because of its discoverer, has been called the bundle of His. In a word, according to Professor Aschoff, an entirely new chapter in cardiac pathology is about to be opened up in the study of this structure and its lesions.

Not a little of the experimental work which demonstrates the truth of these pathologic ideas has been done here in America. Professor Erlanger, of Johns Hopkins, has shown that compression of the bundle of His can, in varying degrees, produce all forms of disturbance of the heart rhythm, even the most serious, and can eventually lead to a fatal termination. The pathologic ideas are also confirmed from the clinical standpoint by a number of English and American observers. Many of the puzzling forms of arrhythmia of the heart, which have so often proved insoluble problems to clinical observers, find a comparatively ready explanation by this new theory. Even the curious set of phenomena known as the Stokes-Adams syndrome, in which there is extreme irregularity of the pulse with stoppage of the heart sometimes that lasts for half a minute or even longer and then gradual resumption of the slow rhythm, and which the hearts of patients suffering from this disorder so frequently exhibit, can be rather readily explained on the score of inflammatory conditions seriously interfering with the conduction of impulses which originate regularly in the auricle, but fail to reach the ventricle because of the heart block that exists.

Sir James Barr emphasized the fact that this as yet remains only a theory, and brought out especially that the question of the conduction of impulses through a muscle band which itself does not contract is a new idea in medicine. There seems to be no doubt that the enthusiasm over recent discoveries has led some of the pathologists and clinicians to minimize the objections to the theory. It is probable that nervous impulses will yet be found to play a rôle coördinate with those which are supposed to be stopped in the bundle of His. In the meantime it is of more than passing interest to realize that something new has arisen in the old field of heart pathology and that the novel theory contains some most suggestive elements which can not fail to help in the understanding of certain cardiac problems, even though eventually it should prove not entirely worthy of acceptance in all the breadth of its present apparent significance.

THE RELATION OF THE MEDICAL EXAMINER TO THE MEDICAL DIRECTOR.

Last week we discussed the relation of the medical examiner to the agent and referred to the fact that many other points remained which it would perhaps be interesting and profitable to take up later.

The relation of the examiner to the home office should be as direct and intimate as possible; the reports should go direct to the home office without passing through the hands of the agent, and any correspondence in reference to cases should be addressed directly to the examiner. Should he be negligent in his duties in any way, the proper remedy lies not in any means of coercion by the agent or the general agent, but in complaint to the medical director, who alone has power of discipline in his department. In a word, it can not be too strongly emphasized that in a properly conducted company the examiner is an officer of the medical department and amenable solely to the medical director for the conduct of his work.

A more frequent personal contact of the medical directors and examiners would conduce to more cordial relations and greater efficiency. We are aware that the position of medical director of a large company is an exacting one, but the chief person concerned in the selection of risks is the examiner, and the mortality experience of the company must depend almost wholly on the care, the wisdom and the honesty with which he does his work. It seems obvious, therefore, that the personnel of the local examiners is the most vital factor in determining the death rates. The chief duty of the director is his selection of the local examiners and the keeping in touch with them, in so far as possible, by personal contact. The state and county societies furnish a convenient place for such contact, and it seems strange that the medical directors are so seldom seen at these societies, whose members, with few exceptions, constitute the most progressive and capable members of the profession. These meetings also afford an opportunity for conferences of the local examiners of an insurance company, which ought to be held at least annually, preferably at the meetings of the state medical societies, either at some unoccupied hour during the session or on the day preceding or following the regular meeting. If an annual meeting of the agents is of sufficient importance to warrant the payment of their traveling and other expenses and the offering of prizes to the most successful, surely similar meetings of the examiners would conduce to better and more effective work, the results of which would ultimately appear in the mortality experience of the company. At such conferences the scientific aspects of life insurance examining should be discussed and the interest of the examiners aroused and stimulated to work for something beyond the mere fee. Under present conditions it may be safely asserted that the great majority of physicians, even among those who are keenly interested in the scientific side of their clinical work, have little or no interest in life insurance examining beyond the compensation derived from it. This is inevitable so long as they have no means of following their insurance cases and of knowing their ultimate outcome. If each examiner were to keep a careful record, preferably a carbon copy, of every examination, as he keeps a history of his clinical patients, and if then the home office were to inform him of every death among the cases he has recommended, and, when possible, of those whom he has declined, it would be possible for him to develop much the same interest in his insurance as in his clinical work. Only in this way can the best work of the examiner be obtained. The most effective service from a professional or scientific man can never be secured on a purely mercenary basis.

There has been a tendency among the medical directors, especially of the American companies, to exaggerate the importance of what might be called the "clerical" as contrasted with the "judicial" function of the local examiner. In the instructions to examiners great emphasis is laid on the importance of recording all the facts, with the intimation that the medical director will do the rest—will determine, from the mere catalogue of facts as to the family and personal history and physical condition of the applicant, whether or not he is a good risk. The effect of this is to lead the examiner to feel that he has done his full duty when he has perfunctorily recorded the facts called for in the application blank, and that there is little call for the exercise of his judgment as to the rating of the risk. Of course, the actual recording of all the facts is important, but a good-sized book full of such could not enable the medical director, who has never seen the applicant, to judge as accurately of his insurability as a careful examination of the applicant face to face.

QUACK DOCTORS AND QUACKERY.

No articles have appeared that have proved so effective in accomplishing their purpose as have those on "patent medicines" by Samuel Hopkins Adams in *Collier's Weekly*. They set the people to thinking, and that was all that was necessary. The sale of "patent medicines" immediately dropped off, and, in some instances, almost to the vanishing point. This is especially true of such over-advertised frauds as Peruna and Liquozone—the latter, it is stated, being almost wiped out.

Another series of the "Great American Fraud" articles by Adams is now appearing in *Collier's*, this time on "Quacks and Quackery." The first of this series was on "The Miracle Workers;" the second on "The Scavengers," and the third, which has just appeared (September 1), is on "The Specialist Humbug." In this article Adams shows up that prince of humbugs, Oren Oneal, in a way that will open the eyes of the gullible public much more satisfactorily than Oneal himself was ever able to do with his "dissolvent method." Coffee of Des Moines, Powell, Madison and other "eminent" eye and ear quacks are placed in the lime light of publicity and their rascally humbugging methods exposed. Undoubtedly the public will begin to think about the advertising quack and his methods which will result in at least checking his inhumane course. In fact, something has already stirred up the officials of Chicago—where quackery is probably more rampant than in any other city in the world—for the corporation counsel has commenced a crusade against the quacks and fake medical institutions in that city.

Adams points out how to tell whether or not the doctor is a quack: "The advertising doctor who, having a 'cure' to sell, is 'editorially endorsed' by any publication, particularly in the religious field, is a quack. The doctor who advertises secret powers, or newly discovered scientific methods, or vaunts a special 'system' or 'method,' is a quack. The doctor who offers to sell, at a price, a cure for any ailment is a quack, and if he professes a 'special interest' in your case and promises reduced rates, he's throwing in a little extra lying for good measure. Finally, the form-letter is a sure sign. You can tell it because it begins 'Dear Friend,' or 'Dear Mr. So-and-So,' or 'My dear Correspondent,' and contains promises that will fit any case. If, however, you are determined to give a trial to one of these 'specialists,' suggest these terms: that, since he *promises* to cure you, you will deposit to his account the full price of the treatment, to be paid him as soon as you are cured, or substantially benefited, and not before. Then and there negotiations will cease. The promising quack will never stand behind his promises. Through this simple expedient one may guard himself against the whole army of medical scamps, for this is the final test of quackery which none of the ilk can abide."

A feature brought out is that one of the quacks, after expulsion from the American Medical Association, still continued to display in his office his certificate of membership as an index of his good standing. It is certainly gratifying to know that the organization has come to mean so much that even the quack and charlatan strives to take advantage of its prestige for his own purpose. In the meantime it must not be forgotten that these articles in *Collier's* supply an inexhaustible amount of material for the warfare with quackery that will be useful any time during the present generation, not alone against the men who are actually exposed, but also against others whose methods will partake of those which have been so mercilessly shown up on the present occasion.

THE LOURDES PILGRIMAGE.

We have not heard that the annual pilgrimage to Lourdes has been discontinued or materially diminished by the almost unanimous protest of the French physicians. It is a difficult matter to handle, and such religio-medical resorts will probably always be in favor with certain classes, notwithstanding the perils they involve. If faith were the power to control man's physical ailments that some claim it to be, such excursions ought to be conducive to the public health, but it is a simple matter of observation and statistics to prove that they are just the opposite. A few cases may be benefited from the psychologic effect, but a much larger number are likely to be made worse, and the aggregation of disease in such places and in such pilgrimages is a special opportunity for the spread of contagion and infection. One need not accept all that Zola has described to admit this; unless the conditions are controlled absolutely by skilled sanitarians with a free hand, evils are inevitable and the difficulties of correct sanitation are specially aggravated when the conditions are all dominated by an implicit religious faith in a miraculous shrine to which necessary sanitary measures would seem almost necessarily sacrilegious. We have examples enough in this country in the way of Eddyism, Dowieism, etc., of the conflict between unenlightened credulity and necessary health measures. The fact that a large number of Roman Catholic physicians, presumably devout Catholics, in France, have indorsed the protest against the Lourdes pilgrimage shows that an enlightened religious sentiment is not blind to the evils supported by too credulous fellow religionists. It is to be hoped that if this pilgrimage is to continue year after year it will soon come under the control of those who can deprive it as far as possible of its dangers to public health.

RAGWEED EXTERMINATION.

Now that the hay-fever season is well on, it is a little remarkable that more has not been said about the abolition, near human dwellings at least, of the plants that are popularly supposed to be its cause. The proposition is perhaps too large a one, but there are a few plants that are said to be especially responsible and have not the excuse of being redeemably esthetic or otherwise useful. Among these is the ragweed, ridiculously called by the botanists ambrosia or food of the gods, which grows in almost every suburban vacant lot, and the pollen of which reddens the trouser legs of every man who traverses them at this season. If it deserves its popular reputation, it is the chief offender. We would not like to see the golden-rod exterminated, and it has at least the merit of not infesting the closer built up regions of human habitation, but the ragweed is pretty nearly everywhere and thrives in the crowded haunts of man as well as in the truly rural districts. In Ohio it seems they have a law against it as a public nuisance, but, like the edicts against Canada thistles and poison ivy, it probably is very little enforced. It may be impossible to exterminate the weed, but it has as little apparent excuse for its existence as far as usefulness or innocuousness to humanity is concerned as any other species of our flora, whether it is really the cause of hay fever, as it is supposed to be, or not.

TUMORS OF THE BRAIN.

The study of tumors of the brain is of especial importance by reason of the brilliant therapeutic results at times attained by means of both surgical and medicinal measures. Non-malignant intracranial neoplasms are not at all uncommon, and careful scrutiny will often lead to accurate diagnosis at a time sufficiently early to justify hope of recovery as a result of appropriate treatment. Even in cases in which recovery can not be brought about, marked relief, particularly from distressing headache can be afforded. The timely institution of treatment will avert, also, such serious dangers as blindness from optic neuritis. The results of an interesting analysis of seventy cases of brain tumor are presented by Dr. Arthur Conklin Brush[1] in a communication read before a recent meeting of the Medical Association of Greater New York. The patients varied from 6 months to 72 years of age; 60 per cent. of the cases occurred in persons between the ages of 20 and 50 years. and this distribution is attributed to the greater frequency of syphilitic tumors during this period. Almost 60 per cent. of the cases occurred in males. In 75 per cent. no etiologic factor could be ascertained. Five of the growths were tuberculous; six occurred during the presence of active syphilis, recovery taking place under specific treatment; two others were found to be syphilitic at autopsy. In two cases heredity appeared to be an etiologic factor. Unfortunately, the symptoms of cerebral tumor are not prompt in appearance and regular in development. In three cases they covered a period of four, five and ten years, respectively. In only eight was the duration from two to eight weeks, and in four of these the lesion was undoubtedly syphilitic. Convulsive seizures were among the most prominent early symptoms. These were general or local or of the nature of petit mal. Defective vision occurred next in frequency as an early symptom. Other common clinical phenomena were headache, with nausea, vomiting and vertigo, ataxic gait, hemiplegia, dementia. Eighteen of the growths were subcortical; 17 were situated in the motor cortical region, 7 in the basilar ganglia, 6 were basilar, 6 cerebellar, 5 in and about the pons. In 14 cases the new growth was found to be a sarcoma, in 11 syphilitic, in 9 a glioma, in 7 tuberculous, in 4 cystic, in 1 an angioma and in 1 a psammoma. Fourteen patients recovered under medicinal treatment; 19 were improved by surgical means, and 13 died. The only drugs that are known to influence favorably the growth of cerebral tumors are mercury, iodin and arsenic. The fact that improvement follows treatment with mercury and iodids is not conclusive evidence that the growth is syphilitic. When medicinal treatment is not succeeded in a few weeks by definite improvement and the new growth can be localized in an accessible situation, surgical intervention should be resorted to. Even then irremediable damage may already have been done and the operation itself may result in paralytic phenomena. For this reason the importance of early diagnosis and prompt and vigorous treatment must be obvious.

THE MINNESOTA HEALTH REGULATIONS.

The laws of Minnesota put the formulation of health rules for the state in the hands of the State Board of Health, and this board has recently published a very complete and elaborate set of regulations, covering nearly all the points of public sanitation. Naturally this has stirred up a little opposition. There are always those who see a restriction of their liberties in salutary regulations. So far as we can see from the copy before us, the rules are reasonable and enforcible, and the fact that their making and interpretation is in the hands of the Board of Health makes it the more easy to abolish or to modify such as experience may show to be impracticable or to work undue hardship to any one. In fact, we believe that the details of such measures should be left as far as possible to an intelligent health board rather than to have them embodied in legislative enactments and only changeable by additional legislation. The rules cover the ground very completely, though we should infer that there are no distilleries in Minnesota, as the possibilities of swill milk seem to have been overlooked. We mention this simply as a suggestion to the Minnesota Board of Health. The State of Minnesota is certainly well off in its health officials.

THE VARIABILITY OF SUPRARENAL PREPARATIONS.

The contribution by Dr. Reid Hunt and the reports of Drs. Sollmann and Brown, appearing in our Pharmacology department this week, represent entirely independent investigations, executed on different animals and by somewhat different methods. They are, however, in striking agreement by showing that the various solutions of suprarenal alkaloids on the market are far from uniform. Hunt's examination demonstrated that to produce equal effects it required of one brand five times as much as of another. Specimens obtained from one manufacturer were of uniformly good quality; one specimen obtained from another manufacturer was good, another from the same firm was inferior, while the products of one of the firms, obtained directly from the company, were uniformly bad. The report of Sollmann and Brown shows that the activity varies commonly from 65 to 100, and one sample was inactive. As pointed out by Sollmann and Brown, these results have a purely negative value; they should not be interpreted as determining the relative value of the various brands, but merely as demonstrating the variability of the products. We feel assured that this is a fault which need only be pointed out to be remedied, and that future examinations will reveal a greater degree of uniformity. It might be regretted that the reports do not mention the names of the preparations, but, under the circumstances, it has been thought best to omit these. The object of the investigation and the publication of the results is not to condemn any firm or any preparation, but to call attention to actual conditions regarding these important remedies. It is believed, too, that the publication of these reports will encourage manufacturers to test and standarize their products more conscientiously so that they may be sure that the claims on the label will be borne out. It is to be hoped that the U. S. Public Health and Marine-Hospital Service may consider it wise to repeat the experiments occasionally and in the future to mention the names of the preparations examined. Similar experimental work has recently been done abroad. Cameron, of Edinburgh, has examined a number of suprarenal preparations on the English market and has found several of the preparations uncertain and variable—the American preparations, however, standing well in the investigation. American firms have taken the lead in the manufacture of preparations of suprarenal active principle, and it is hoped they will strive to keep up the standard and so maintain the lead.

Medical News

ALABAMA.

New Sanitarium.—The new sanitarium of Dr. Miles A. Copeland, near Birmingham, is now open, with accommodations for 12 patients.

Fined for Omission to Report.—Twenty-four warrants against physicians of Birmingham were issued August 16, for failure to submit obstetric reports to the city physician, and several of these physicians were fined $1.00 and warned that in case of future offense a heavier fine would be assessed.

Commends State Authorities.—In a public statement issued August 4, State Health Officer Dr. William H. Sanders, Montgomery, commends the health authorities of New Orleans and Louisiana for the care they are exercising to keep yellow fever out of the country. He states that the candor and honesty of the New Orleans physicians has done much toward allaying public fear in this regard.

Ill and Injured.—Dr. James E. Seay, Pratt City, is recovering from the injuries sustained in an accident on the Frisco railroad in July.——Dr. Wilson L. Heflin, Roanoke, was seized with an attack of vertigo August 2, but is now reported to be improving.——Dr. J. Ross Snyder, Birmingham, who has been suffering from typhoid fever at Hillman Hospital, is convalescent, and has been removed to his home.——Dr. Thomas E. Callan, Scottsboro, has been ill for several days in a hotel at Gadsden.

ARKANSAS.

Personal.—Dr. Arthur G. Harrison, Warren, has been selected by the State Board of Health to succeed John M. Young, Little Rock, as physician to the Arkansas Deaf Mute Institute.——Dr. Jefferson D. Southard, Fort Smith, has been appointed physician of Sebastian County, vice Dr. James W. Breedlove, deceased.——Dr. Arthur C. Jordan, Pine Bluff, fractured a rib and sustained serious contusions in a runaway accident, August 19.

CALIFORNIA.

Smallpox.—The Secretary of the State Board of Health report's isolated cases of smallpox at Red Bluff and Dunsmuir.

Funds for Fever Fight.—The executive committee of the San Francisco Relief Corporation has appropriated $28,000 for the use of the health board in its war against typhoid fever.

College Notes.—The Oakland College of Medicine and Surgery opened for its fifth annual session August 21.——The College of Physicians and Surgeons, San Francisco, is to be rebuilt on Fourteenth street, between Woodward avenue and Jessie street, at a cost of about $50,000.

Tuberculosis Clinic Opened.—A free dispensary for the treatment of tuberculosis, connected with the Medical Department of the University of Southern California, Los Angeles, was opened August 6. The dispensary is under the direction and supervision of Dr. Frances M. Pottenger, medical advisor of the Anti-Tuberculosis League, assisted by Drs. W. Jarvis Barlow, George H. Kress and Sleeper.

Typhoid Fever.—The mysterious disease reported among the Japanese laborers in Pasadena has been pronounced to be "typho-malarial" fever. Two deaths have been reported.——On August 8 three patients with typhoid fever were removed to the hospital from the relief camp, Mariposa. The camp was located next to a pond of stagnant water and had no kitchen.

Personal.—Dr. Fred P. Clark has been elected superintendent of the Stockton State Hospital, vice his father, Dr. Asa Clark, resigned. Dr. Asa Clark will take charge of the sanitarium which has been under the direction of his son at South and Center streets, Stockton.——Dr. Charles C. Falk has been appointed federal quarantine officer for the port of Eureka, vice Dr. Clarence V. Thompson, resigned.

Sanitation Committee Report.—The sanitation committee of the San Francisco grand jury reported that general health conditions throughout the city are good and that the Board of Health has been active and conscientious in its work. The grand jury expresses to the 400 physicians who worked voluntarily in coöperation with the committee during the weeks following the earthquake and fire, the gratitude of the people of San Francisco.

Additional Sanitary Inspectors.—The San Francisco Board of Health, on the recommendation of the county medical society, has appointed the following medical sanitary inspectors: Drs. Herbert Wallen, Paul Castelhun, Philip Collischon, G. O. Culver, Morton R. Gibbons, A. B. McConnell, Harry R. Oliver, Clarence Quinlan, Walter J. Williams, Harry P. Roberts, E. W. Alexander, Frederick G. Canney, Roland E. Hartley, Charles Clark, Chester Harris, and M. McCauney.

Lane Lectures.—The annual course of Lane Medical Lectures was given in Cooper Medical College, San Francisco, by Dr. John McVail, Glasgow, Scotland, on August 20 and the five following days. The general subject of the lectures was "The Prevention of Infectious Diseases," and dealt with the progress of modern sanitary administration with a description of public health organizations of towns and counties, the abolition of typhus fever by sanitation, the results of modern house conditions, and the importance of building regulations. Then were considered in order, plague, typhoid fever, measles, scarlet fever, smallpox, tuberculosis, and finally the general question of the ethics of disease prevention, showing that the result of the advance in sanitation, vaccination, isolation and health effort has been to improve the race physically and morally, and the outcome is most encouraging for the future.

Hospital News.—The president of the University of California has approved the plan of Dr. Arnold A. D'Ancona, dean of the medical department of the institution, and his confrères, of converting the middle building of the affiliated college grounds south of Golden Gate Park, into a modern hospital, having a free clinic. It is estimated that $50,000 will be required to make the necessary changes, and of this amount $20,000 is available at the present time.——Mrs. Sylvester is erecting a large sanitarium on Wyandotte ranch, near Chico.——Dr. Thomas J. Randall, Los Angeles, turned the first spadeful of earth for the foundation excavation of the new Sunset Hospital, August 13.

COLORADO.

July Deaths.—During July 799 deaths were reported in the state, equivalent to an annual mortality of 14.16 per 1,000. Of the deaths 19 were caused by typhoid fever, 5 by diphtheria and 4 by scarlet fever, and 33 stillbirths were reported.

Dr. Keith Convalescent.—Dr. John G. Keith, Leadville, who has been suffering from complete paralysis as the result of a lightning stroke last May and has been under treatment at St. Luke's Hospital, Denver, has returned to his home convalescent.

Communicable Diseases.—During July 173 cases of typhoid fever were reported in the state, 105 cases of scarlet fever, 31 cases of diphtheria, and 30 of smallpox. As compared with the previous month, there was a decrease of 5 cases of diphtheria, 3 of scarlet fever, 35 cases of smallpox, and an increase of 110 cases of typhoid fever.

DISTRICT OF COLUMBIA.

Communicable Diseases.—A slight increase occurred during the week in diphtheria; scarlet fever showed a decrease of four cases; typhoid fever continued to increase, there being 74 new cases reported and only 35 discharges, 4 of which were by death, leaving 296 under treatment at the close of the week, as compared with 257 at the close of the preceding week.

Mortality for the Week.—The mortality of the week ended August 18, when compared with the record of the previous week of 1905, shows a gratifying improvement, there being only 103 deaths as compared with 136 during the week ended August 11, and 107 during the same week of 1905. Of the decedent 63 were white and 40 colored, which represents the following death rates per 1,000, per annum: White, 14.1; colored, 21.9; and, total population, 16.4. The principal causes of death were diarrheal diseases, 14; consumption, 13; disease of the heart and cancer, each 5; typhoid fever, 4; and cerebral hemorrhage, bronchitis and meningitis, each 2.

ILLINOIS.

Personal.—Dr. Albert S. Wall, Champaign, has returned after four months in Europe.——Dr. Lewis H. Skaggs, Ellsworth, was overcome by the heat, August 23, but is improving.

Training School at State Hospital.—Dr. Vaclav H. Podstata, superintendent of the Illinois Northern Hospital for the Insane, Elgin, announces the opening of a training school for attendants and nurses on October 1. The school will have a three-years' course and the attendants will be given more time off duty and the hours in various quarters will be shortened.

Advocate Septic Tank.—As the result of a conference held between the Secretary and Assistant Secretary of the State Board of Health and the directors of the State Board of Water Survey, Urbana will probably have in a short time a modern septic tank for the purpose of demonstrating to the officials of the various municipalities the advantages of this method of sewage disposal.

Consumption Camp Started.—The members of the Chicago Tuberculosis Institute have perfected plans for the erection at Dunning of portable houses for patients suffering from tuberculosis, who will be given treatment at the new camp which is now being established. The houses consist of dormitories, 26 by 44 feet, and include two porches, a kitchen and a dining-room. Three of the cottages are now ready and the camp, with accommodations for 20 to 30 patients, will probably be opened this week.

Communicable Diseases.—Typhoid fever is reported to be prevalent in Alton and the necessity of boiling all drinking water is urged.——Joliet reports four cases of scarlet fever.——Diphtheria has been prevalent in Brereton, and the situation is being investigated by an official of the State Board of Health, who recommended that every house in which there had been a case of diphtheria should be properly disinfected and fumigated, and that all clothes and wearing apparel should be disinfected. He ordered the two families at present under quarantine to be released and the houses fumigated.

Chicago.

College Commencement.—The twelfth annual commencement exercises of Illinois Medical College were held August 23, when degrees were conferred on a class of fifty by Dr. Heman H. Brown, president of the college.

Offers School for Deaf.—Comptroller McGann has received an offer from a woman philanthropist to erect a school for the blind on the Gage farm. The donor proposes to make the school sectarian and expects to put up a building to cost about $50,000.

Typhoid Fever in Rogers Park.—The Health Department has discovered 6 cases of typhoid fever, one of which was fatal, between Morton street and Touhy avenue, Rogers Park. In this location the residents have no city water service, and are obliged to depend on well water or purchased water for drinking or household purposes.

INDIANA.

To Teach the People.—Dr. William J. Scott, Kokomo, health officer of Howard County, has been authorized by the Board of County Commissioners to have printed for distribution 2,000 pamphlets treating of consumption and typhoid fever, and the best methods of prevention and treatment of these diseases.

Personal.—Dr. and Mrs. Albert E. Bulson, Fort Wayne, have returned from a three months' trip abroad.——Dr. Charles E. Grayston, Huntington, has been appointed district optician and oculist for the Erie railroad.——Dr. Anna M. Lemon Griffin, formerly a practitioner of Muncie, has been sent to the State Hospital at Logansport by the authorities of Kokomo. She is believed to be temporarily deranged.——Dr. Charles H. Eckert, Marion, was operated on at Fort Wayne, August 22.——Dr. J. Robert Norrel, Richmond, has been elected secretary of the local board of health to fill the unexpired term of Dr. T. Henry Davis, formerly secretary, and at present president of the State Board of Health, resigned.

Communicable Diseases.—The Secretary of the Kendallville Board of Health reports that only two cases of smallpox have developed in that place this summer and anticipates no further trouble. The quarantine has been lifted.——There are about fifteen cases of smallpox in Peru, two of which are in South Peru, and quarantine is in force.——At Hoagland there is reported to be six cases of diphtheria with one death, and the county health officer has quarantined the homes in which the cases were found.——Columbia City has a number of cases of typhoid fever and the city water is being analyzed.——An epidemic of typhoid fever is said to be existing at Russiaville, where 20 cases have already developed. The health authorities have decided the disease was due to the use of inferior and polluted drinking water.

Slaughter-House Regulations.—The State Board of Health has drawn up an ordinance for the control of slaughter-houses, butcher shops, meat and fish markets, and public eating-houses, providing that the animals butchered shall be absolutely sound; that the slaughter-houses shall be made and kept sanitary, and that the offal shall be tanked, cremated, or buried; that cold storage facilities must be provided; that employés must be clean as to personal habits and clothing; that the slaughter-houses shall be provided with ample lavatory facilities; that swine must not be fed on offal; and that meats shipped from other states shall be accepted if the place of preparation is inspected. The regulations for butcher shops, meat and fish markets provide that they shall be screened from May 1 to November 1, and that plants and tools shall be kept clean. The regulations for the public eating houses provide that they shall be kept clean, well lighted and sanitary; that the tables, linen, dishes, utensils, etc., shall be kept thoroughly cleansed; that all employés shall be personally clean and shall wear clean clothing; that all waste water shall be removed and placed in proper receptacles; that all cellars and storage places for vegetables and meats shall be thoroughly disinfected whenever required, and shall be kept clean and free from all decaying matter. Rats, mice, and other vermin shall be excluded from all storage places. All hotels, inns, taverns, boarding-houses and eating-houses shall be subject to public inspection at any and all times.

IOWA.

Personal.—Dr. Frank D. Ayres, Sabula, suffered some severe burns on the face and eyes by the explosion of a gas generator at his residence, August 6.——Dr. Peter H. Schroeder, Traer, sailed for Europe August 25, on the *Philadelphia*.——Dr. Howard E. Campbell, Anita, is seriously ill with heat exhaustion.

Medical Society Meeting.—Botna Valley Medical Society held its annual meeting in Atlantic August 13 and decided to meet in 1907 at Avoca. The following officers were elected: Dr. George A. Spalding, Avoca, president; Dr. Thomas B. Morris, Atlantic, vice-president; Dr. Augustine Grant, Minden, secretary (re-elected); Dr. Harry D. Spencer, Oakland, treasurer; and Drs. William F. Graham, Athens, George A. Cassidy, Shelby, and Harry D. Spencer, Oakland, censors.

State Board Elected.—At the annual meeting of the State Board of Health, July 23, Dr. Fred W. Powers, was elected president and Dr. Josiah F. Kennedy re-elected secretary. Prof. Henry Albert, Iowa City, was elected director of the state laboratory of bacteriology and bacteriologist of Iowa, and Prof. C. W. Kinney, Des Moines, was elected chemist of the board. On the re-election of the secretary, he tendered his resignation, to take effect Jan. 31, 1907. His resignation was accepted and Dr. Louis A. Thomas, Red Oak, was elected to the position and authorized to assume his duties Feb. 1, 1907.

KANSAS.

Infectious Diseases.—The city sanitary department of Topeka reports under quarantine 7 cases of typhoid fever and one case of scarlet fever.

Epidemic of Dysentery.—It is reported that an epidemic of dysentery is afflicting the country north and west of De Soto. Seven deaths have occurred in the last ten days.

Contract Let for Medical Building.—The administration building of the Eleanor Taylor Bell Memorial, the Rosedale adjunct to the Kansas University Medical School, for which the contract has been let, it is said, will cost $100,000, with equipment, and is to be ready for occupancy this fall. The general hospital, the first of the series, is practically completed at a cost of $30,000.

Sanitary Laws Must Be Enforced.—Dr. S. J. Crumbine, secretary of the State Board of Health, is endeavoring to enforce the laws concerning sanitary conditions of the state. He recently issued orders for the fumigation of every schoolhouse in the state during the vacation period. In reply to a letter from a county attorney as to what he should do about it if the order were disobeyed, Dr. Crumbine gave the following citation from the general statutes: "The health officers of the several local boards throughout the state shall perform such duties as this act, the local board of health, or the State Board of Health, shall require. For any failure or neglect of said officer to perform any of the duties prescribed in this act, he shall, on conviction thereof, be fined $10 for each and every offense."

KENTUCKY.

Tuberculosis Hospital to be Built.—The Louisville city council has agreed that immediate steps must be taken to provide temporary quarters at the present city hospital, Louisville, to accommodate the tuberculosis patients. It is proposed to put up a building to cost about $3,000.

Typhoid Fever.—An epidemic of "typho-malarial" fever is said to be raging at Farmer; 25 cases are said to exist and 3 deaths are reported.——The State Board of Health has issued circulars containing directions for the prevention and care of typhoid fever.——An epidemic of typhoid fever is reported at Midland City in the eastern part of Bath County; 30 cases have been reported and several deaths have occurred.

Personal.—Dr. Florence Meder, third assistant physician at the Western Kentucky Hospital for the Insane, Hopkinsville, has accepted a similar position at the Eastern Kentucky Hospital for the Insane, Lexington, and will assume her new duties September 1.——Dr. Malcolm H. Yeaman, Lakeland, has, it is reported, *decided to resign as superintendent of the* Central Kentucky Hospital for the Insane.——Dr. Meverell K. Allen, health officer of Louisville, who has been in Europe since June, returned August 16.——Dr. Llewellyn P. Spears has succeeded Dr. James W. Guest as physician for the eastern district of Louisville.——Dr. A. D. Park, Lakeport, who has been seriously ill with typhoid fever, is convalescent.

LOUISIANA.

Consolidations.—Arrangements for the consolidation of the Tulane University of Louisiana Medical Department and the New Orleans Polyclinic were consummated, August 30, at the meeting of the Board of Administrators of the Tulane Fund. The Polyclinic will thus become the postgraduate department of the college.

The New Iberia Case of Yellow Fever.—The one case of yellow fever at New Iberia, 125 miles from New Orleans, is still a mystery. The patient, a mulatto boy 12 years of age, has apparently recovered from the disease. The physicians agree that the case was unmistakably one of yellow fever, but thus far they have been unable to determine the source of the infection. Thorough fumigation and disinfection of the town has been carried out by the State Board of Health, and no other cases are expected to occur.

MASSACHUSETTS.

Outdoor Treatment for Tuberculosis.—The State Tuberculosis Commission will, it is reported, recommend to the legislature a campaign in every slum and tenement district of the state, to apply the home cure and outdoor sleeping for the treatment of tuberculosis.

Personal.—Dr. Charles S. Millet, Brockton, has been appointed secretary of the State Tuberculosis Commission.——Dr. J. F. A. Adams has been appointed chairman and Dr. John P. Rand, Monson, secretary of the trustees of the Massachusetts State Sanatorium for the Treatment of Tuberculosis, Rutland.——Under the new state law, which came into operation September 1, Dr. John H. Bannon has been appointed school physician for Lawrence.

Dedication of the New Harvard Medical School.—The dedicatory exercises of the new Harvard medical buildings will occur September 25-26. On Tuesday afternoon the dedicatory exercises will be held at the new buildings, followed by an afternoon tea. In the evening a reception will be given by the alumni and the officers of the Harvard Alumni Association at the Boston Medical Library. On Wednesday morning there will be literary exercises and the conferring of honorary degrees at Sandars' Theater, Cambridge, followed by informal reunions of the medical classes. In the afternoon the triennial banquet of the Harvard Medical Alumni Association and invited guests will be held at Memorial Hall.

MICHIGAN.

Capital Stock Increased.—The Grand Rapids Medical College Equipment Company, owners of the Grand Rapids Medical College, have increased their capital stock from $5,000 to $15,000.

Carstens for Mayor.—Dr. J. Henry Carstens has announced himself as a candidate for mayor of Detroit on the Republican ticket. His platform he announces to be opposition to the eighteen-year franchises proposed for the Detroit Union Railway and reduction in street-car fares. He believes that the people are entitled to a lower rate than six tickets for a quarter.

Personal.—Drs. G. E. Stripp and Henry B. Carey of the attending staff of the Michigan State Hospital for the Insane, Kalamazoo, have resigned, Dr. Stripp to practice medicine in the state and Dr. Carey to accept a chair in a California college.——Dr. George R. Pray, Jackson, physician to the State Prison, was brutally assaulted August 14.——Dr. Henry M. Leach, Saginaw, while returning from Bridgeport, was thrown from his buggy in a collision and was rendered unconscious. He is now reported to be improving.

July Mortality.—During July, 2,779 deaths were reported to the department of state, an increase of 29 over the preceding month and 279 over the corresponding month of 1905. This mortality is equivalent to an annual death rate of 12.7 per 1,000. Of the decedents, 627 were infants under 1 year of age and 678 individuals aged 65 years and over. Diarrheal diseases of infants caused 259 deaths; accidents and violence 222, of which 50 were from drowning; tuberculosis, 220; cancer, 147; pneumonia, 84; whooping cough, 43; typhoid fever, 33; meningitis, 27; measles, 23; diphtheria, 22, and scarlet fever, 14. During the month 3 deaths occurred from lightning. Tetanus was given as the cause of 10 deaths, in 2 of which the fatal result was due to the careless handling of explosives.

Wayne County in Line.—The secretary of the Wayne County Medical Society has issued a pamphlet to call the attention of the physicians of Wayne County who are not members of the local organization to the advantages now offered to its members by the society, and to secure the interest and support of all practitioners of medicine in the completion and perfection of the organization of the profession and of the county. For the annual dues of $4 the following advantages are now offered: 1. Membership in the Wayne County Medical Society. 2. Membership in the Michigan State Medical Socity. 3. The Journal of the Michigan State Medical Society. 4. Privileges of medical defense. 5. Eligibility to membership in the American Medical Association. 6. The advantages to be derived from the completion of medical societies in Wayne County.

Communicable Diseases.—The health officer of Cadillac says that he has 80 lumbermen quarantined in a lumber camp in Henderson County on account of diphtheria. Several cases have been found and one camp has been converted into an isolation hospital.——Typhoid fever is epidemic in Three Oaks, 21 cases have been reported, with 1 death, and 3 patients are reported to be in critical condition. On examination of the standpipe which supplies the town with water, the decomposing bodies of hundreds of young sparrows were found in the water. The standpipe was emptied and is to be cleaned.——Traverse City reports 15 cases of typhoid fever.——Mass City and Greenland, Ontonagon County, are suffering from an epidemic of typhoid fever. There have been 35 cases reported, with 5 deaths.——Several cases of typhoid fever, traceable directly to the milk supply, are reported from Allegan.

MINNESOTA.

Buried with Full Military Honors.—All the officers of the First Infantry N. G., Minnesota, and the Minneapolis companies of the regiment met at the armory August 21 and marched to Lakewood Cemetery, headed by the First Regiment band, and there buried Dr. Reynaldo Juan Fitzgerald, with full military honors. The active pallbearers were officers of the regiment.

Sanatoria in Rochester.—Patients for St. Mary's Hospital are coming in such numbers as to overtax its capacity. To relieve the congestion, two sanatoria are now in process of construction, the first under the charge of Dr. John E. Crewe, who has purchased the E. A. Knowlton residence, and is fitting it up at an expense of about $40,000, and the second is being built by Mrs. Charles E. Chute, which will contain about 35 rooms, involving an outlay of about $10,000.

License Revoked.—The State Board of Medical Examiners has revoked the license of Dr. Van Damme, Minneapolis, convicted of illegal practice.——Dr. Theron H. Bly, who is serving a sentence in the state prison at Stillwater, has been notified that his case is pending, and tnat the revocation of his license will be voted on at the next meeting of the board to be held about October 1. The board is unanimously in favor of revoking the license of every practitioner against whom a case can be proved.

MISSOURI.

Busy Year for Ambulances.—The ambulances of the health department of St. Louis during the last fiscal year made 10,759 calls, covering a distance of 54,749 miles.

May or May Not be Vaccinated.—In Kansas City this year for the first time the schools will admit pupils whose arms do not show the marks of successful vaccination. Six months ago the council passed an ordinance leaving it optional whether or not the residents of the city shall be vaccinated.

Diseases and Deaths in St. Louis.—During the week ended August 20 there were 215 deaths in St. Louis, an increase of 31 as compared with the preceding week. Gastrointestinal diseases caused 24 deaths; consumption and circulatory diseases, each 23; accidents, including violence, 16; cancer, 13, and marasmus and inanition, each 11.

Asylum Changes to be Made.—At a meeting of the Board of Public Improvements, St. Louis, at which the health commissioner and superintendent of the insane asylum were present, plans were made for the improvement of the asylum under the appropriation recently made. It was decided that provision should be made for 1,600 or 2,000 new patients and that the patients should be housed in groups of 40 each, with one attendant allowed for every 10 patients. For the violent insane a separate building is to be erected to accommodate 160. All the buildings will be provided with offices and sleeping rooms for at least one physician and two or three attendants. A separate residence building is to be erected on the asylum grounds for the superintendent and a separate building also for the accommodation of attendants and outside help. The present asylum building, designed to accommodate 400 patients, now contains 640.

Tuberculosis by Districts.—Statistics have been compiled by the clerk of the St. Louis board of health, showing the number of cases of tuberculosis and the deaths from that disease in each of the seven sanitary districts. The third district, located east of Jefferson Avenue and between Franklin and Chouteau avenues, shows a greater aggregation of cases and deaths than any other district. In the first district, with a population of 77,075, there were 243 cases and 182 deaths; in the second, with a population of 98,336, there were 249 cases and 178 deaths; in the third, with a population of 68,159, there were 267 cases and 190 deaths; in the fourth, with a population of 119,056, there were 264 cases and 183 deaths; in the fifth, with a population of 77,522, there were 192 cases and 130 deaths; in the sixth, with a population of 130,975, there were 271 cases and 187 deaths, and in the seventh, with a population of 123,895, there were 260 cases and 162 deaths.

NEW HAMPSHIRE.

Food Adulteration.—The State Board of Health reported recently that as a result of an examination of 408 samples of prepared foods, 186 were found adulterated, misbranded or below standard.

Donation to Hospital.—Mr. J. J. Glessner of Chicago and Mrs. Garrett A. Hobart of New Jersey, widow of the late Vice-President, have each subscribed $5,000 for the new hospital at Littleton.

Polluted Well Causes Typhoid Fever.—There is an epidemic of typhoid fever in West Canaan. Thirty cases have been traced to the public well and an analysis of the water showed that it was badly polluted. The well has been closed.

NEW YORK.

Typhoid Fever from Bad Wells.—As a result of drinking from polluted wells, five cases of typhoid fever are reported from West Lyons, one of which has resulted fatally.

Did Not Discontinue Practice.—A. Arthur Huntley, Cuylerville, who was charged with illegal practice of medicine on the ground that he had not passed the state board examination, was arrested for a second time on account of his failure to discontinue practice and had his preliminary examination before the police authorities of Geneseo, was bonded for $500, and was held to the Livingston County grand jury.

New York City.

Much Trachoma.—The commissioner general of immigration reports that during the last 60 days 10 persons, on an average, afflicted with trachoma, were deported from New York City each day.

Personal.—Dr. William S. Bainbridge has been elected adjutant professor of surgery and has been assigned to one of the clinics in that department in the New York Policlinic Medical School and Hospital.——Dr. John Warren sailed on the *Lucania* for Liverpool, last week.——Dr. Louis L. Seaman has returned from his trip to East and South Africa.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended August 25, 589 cases of tuberculosis and 151 deaths; 158 cases of diphtheria and 14 deaths; 101 cases of typhoid fever and 22 deaths; 51 cases of measles and 7 deaths; 46 cases of scarlet fever and 1 death; 27 cases of whooping cough and 8 deaths; 9 cases of cerebrospinal meningitis and 10 deaths; 3 cases of smallpox and 4 cases of varicella, a total of 988 cases with 213 deaths.

Favor Removal of Isolation Hospital.—The comptroller is in sympathy with the department of health and the citizens who advocate the removal of the hospital for contagious diseases from Kingston Avenue, Brooklyn, to Barren Island or some other suitable location.——The board of health has applied for an additional appropriation of $325,000 more for a diphtheria pavilion and this will come up for consideration before the board of estimates in September.

Vital Statistics.—The department of health reports that 18,928 deaths occurred during the quarter ending June 30, or 632 more than were reported for the corresponding quarter of 1905. The respective annual death rates are 18.29 and 18.25 per 1,000. During the same period there were 25.692 births. Tuberculosis claimed 2,653; pneumonia, 1,527, and violence, 1,223, including 67 homicides and 191 suicides. Of children under 5 years of age 6.237 died. During the year 8.967 deaths occurred in tenements, 6,362 in institutions and 2,936 in dwellings.

New Officers for Health Department.—The following officers have been suggested by the acting medical officer of the department and approved and appropriations made by the board of estimates: Chief clerk, with a salary of $4,000; medical inspector, $2,100; two sanitary inspectors, $2,100 and $3,000, and inspector of food in charge of corps, $2,550. Five clerks, two chemists, a laboratory assistant and several other minor appointments were also provided for. The board has asked for an automobile, to cost not more than $3,000, for the use of the assistant sanitary superintendent of the borough of Manhattan. The board of aldermen has been requested to allow the department this automobile.

NORTH CAROLINA.

Medical Department Opens.—The medical department of Wake Forest College opened August 29, and reports an encouraging outlook for a successful year.

Hospital Completed.—The hospital connected with the Wake Forest College is almost completed and will soon be available for the use of students and private patients.

Personal.—Dr. Lewis M. Gaines has returned to Wake Forest College from his vacation.——Dr. Watson S. Rankin of the medical faculty of Wake Forest College, who has spent the summer in Boston, has returned.

OHIO.

Typhoid Fever in Toledo.—Twenty cases of typhoid fever are reported in Toledo in the territory bounded by Cherry and Grange streets.

Physicians Do Not Report Births.—As the result of the failure on the part of the Cleveland physicians to report the births, only 261 were reported for the year ended March 31, 1906. The penalty for failure to make reports has never been enforced, it is said.

Gift to Library.—It is reported by the Associated Press, Cincinnati, that General E. P. Walker, recently deceased, bequeathed to the Lloyd library, Cincinnati, his entire library and collection of manuscripts, and has in addition given a fund of $30.000 to be devoted to the securing of qualified experts to make original investigations in the practice of medicine and pharmacy and a study of the specifications of medicine. The restriction in this direction is that the researches are not to be confined to the theoretic side of medicine.

Personal.—Dr. Robert W. Purdy, Bradyville, is reported to be seriously ill with brain disease.——Dr. William Brundage has been made assistant physician to the Columbus State Hospital, vice Dr. William Richardson, resigned.——Dr. E. H. Rorick, superintendent of the State Institution for the Feeble-Minded, Columbus, sailed for Europe August 11.——Dr. Mark Millikin has been re-elected health officer of Hamilton, and Drs. Linus H. French, Clyde W. Hodges and John A. Burnett, district physicians.——Dr. Francis M. Fitton was appointed to fill the position of health officer until the return of Dr. Millikin, who is now in Colorado for his health.——Dr. Thomas C. Parks, Akron, has been appointed a member of the board of censors of Starling Medical College, Columbus.——Dr. John H. Lowman, Cleveland, who was operated on for appendicitis a few weeks ago, is convalescent and has been removed to his summer home.——Dr. Myron S. Clark, Youngstown, has been appointed pension examiner, vice Dr. Albert L. King, deceased.

Faculty Changes at Starling.—The Starling Medical College opens for the fall term September 13. The following changes in the faculty are announced: Dr. Starling Loving, dean, resigned, and Dr. Charles S. Hamilton, elected in his place; Dr. Frank Winders, registrar, vice Dr. Curtis C. Howard; Dr. D. Tod Gilliam was made emeritus professor of gynecology, and Dr. Earl M Gilliam advanced to the chair of gynecology; Dr Isaac B. Harris, professor of physical diagnosis; Dr. Frank Winders, professor of applied therapeutics; Dr. Harry W. Whitaker, associate professor of theory and practice to succeed Dr. John H. Upham, promoted to associate professor of therapeutics and practice of medicine; Dr. Starling Loving, clinical professor of theory and practice of medicine; Dr. Joseph H. Jones, associate professor of materia medica; Prof. Clair A. Dye, lecturer on materia medica; Dr. Sylvester J. Goodman, assistant to the chair of operative and clinical surgery; Dr. Wells H. Teachnor, assistant to the chair of obstetrics, and Dr. P. D. Shriner, clinical demonstrator in obstetrics.

PENNSYLVANIA.

To Prevent Spread of Whooping Cough.—State Health Commissioner Dixon has ordered the placarding of houses in which whooping cough exists, the placards stating, "All persons are notified of the presence of this disease and are warned of the danger of visiting or coming in contact with those suffering from it."

Warning to Hotel Stewards.—A special agent sent by the state dairy and food commissioner attended the meeting of the International Association of Hotel and Club Stewards, in session at Niagara Falls this week. With the agent were sent 75 samples of adulterated foods collected by the department agents throughout the state. The object was to warn the stewards against purchasing adulterated foods for use in hotels and clubs.

Personal.—Dr. Fred E. Kress has been made physician of the Lilly, board of health.——Dr. William N. Stein has been reelected president of the Shenandoah board of health.——Dr. Gustav T. Fox and family, Bath, have sailed for Europe.——Dr. Thomas N. McKee, Kittanning, is suffering from an infected wound of the foot.——Dr. Oscar Lindenmuth, Ringtown, has been placed in charge of the *x*-ray department of the Indiana State University, Indianapolis.——Dr. Calvin H. Elliott, Harrisburg, who was operated on for appendicitis at the Medico-Chirurgical Hospital, Philadelphia, August 6, is rapidly improving.

Hospital News.—After five years of agitation and controversy, it has finally been decided that Pittsburg is to have a United States Marine Hospital on the old arsenal site at Thirty-ninth Street and Penn Avenue.——The directors of the Washington City Hospital Association have decided on the location for a new hospital at the corner of Donnan Avenue and Second Street. The new building is expected to cost about $25,000.——The Alfred O. Deshong sanitary cottage for the treatment of patients suffering from tuberculosis or other communicable diseases originating in the Chester Hospital, has been turned over to the latter institution. The cottage was built and donated by Alfred O. Deshong, Chester.——A new hospital is to be established at Siverly.

Typhoid Epidemic.—An epidemic of typhoid is said to exist in Freedom township, where three deaths have already occurred.——Five cases of typhoid fever are reported in one family at Hatboro.——Typhoid cases have greatly increased in McKeesport during the last few days.——Oakmont reports 30 cases of typhoid fever and Verona 40 cases.——Pittsfield has 7 cases of typhoid. reported to have been imported from Atlantic City, N. J.——The alarming condition of the typhoid situation in Pittsburg is evidenced by the posting of warnings against the drinking of unboiled water.——Typhoid fever has broken out at Berwyn and Devon, 18 cases of the disease existing at

written had a record of only 3,715, of whom 2,377 are males and 1,338 females. The leper problem is stated to be far from an unsatisfactory solution. The new colony which was opened at Culio (see The Journal, July 28, 1906, page 283), will be the beginning of a new order of things in the care of these unfortunates. A number of pictures illustrating the work of the bureau of health forms an interesting addition to the book. Among them are pictures of the board of health ambulance, the old buildings of the San Lazaro Leper Hospi- tal at Cebu and the present leper hospital, the Sampaloc Hos- pital at Manila, a group of American sanitary inspectors and one of assistant inspectors and sanitary police, a board of health station in the San Nicolas district, Manila; types of the Filipino, Spanish and American houses in Manila; the Nipa district, the municipal slaughter house and St. Paul's Hospital, Manila. There are numerous illustrations of other points of interest in and around Manila and in other parts of the islands.

CANADA.

Ontario Association Election.—The annual meeting of the Ontario Medical Association was held in Toronto August 20. After a short executive session the officers were re-elected and it was decided to meet in Toronto in 1907. Dr. George A. Bingham, Toronto, was re-elected president, and Dr. Charles P. Lusk, Toronto, secretary.

McGill University to Honor British Doctors.—Sir Thomas Barlow, Bart., F.R.S.; Sir William Broadbent, Bart., F.R.S.; Sir Victor Horsley, F.R.S., and Dr. T. Clifford Allbutt, F.R.S., have been recommended by the board of governors of McGill University to receive the honorary degree of LL.D. of that institution. The degrees will probably be presented *in absentia* at the next convocation.

Montreal's Annual Medical Report.—According to the annual report of the medical health officer, Dr. L. Laberge, Montreal, for the year 1905, the average death rate of the city per 1,000 of the population was 20.6. This was 0.2 less than in 1904. The birth rate was 0.15 per 1,000 higher than in 1904. The average of births for a period of 19 years has been 37.92 per 1,000. The birth rate in Montreal is higher than in Toronto by 13.81 per 1,000. The marriages in Montreal in 1905 were 10.31 per 1,000, which is an increase of 0.10 over 1904.

Canadian Medical Protective Association.—That this society is progressing very favorably was shown by the annual report of its president, Dr. R. W. Powell, Ottawa, at the annual meeting in Toronto, August 20. He stated that it has now a membership of about 450, has never lost a case it has undertaken to defend, is sound financially and promises to do a great deal of good for the Canadian medical profession. Dr. R. W. Powell, Ottawa, was re-elected president, and Dr. Fenton Argue, Ottawa, secretary-treasurer in the place of Dr. J. A. Grant, Jr., Ottawa, resigned.

Canada Association Meeting.—The thirty-ninth annual meeting of the Canadian Medical Association, held in Toronto August 20, was only an executive session, owing to the meeting of the British Medical Association. The attendance was about 75, and the chief item of business was the reception of the report of the committee on reorganization, which was presented by the chairman, Mr. I. H. Cameron. The report took the form of a proposed new constitution and by-laws patterned somewhat after the constitutions of the American Medical Association and the British Medical Association. After some discussion it was decided that the subject should be thoroughly dealt with next year. Montreal was selected as the place of meeting in 1907. Dr. A. McPhedran, Toronto, was re-elected president; Dr. H. B. Small, Ottawa, was re-elected treasurer, and Dr. George Elliott, Toronto, was re-elected general secretary.

FOREIGN.

Pettenkofer Prize Awarded to Schaudinn.—The prize of $300 from the Pettenkofer endowment at Munich has been awarded to the recently deceased Fritz Schaudinn for his discovery of the spirochete of syphilis, and has been paid to his widow at Hamburg.

Adolf Witzel Endowment.—The recently deceased professor of dentistry at Bonn, Adolf Witzel, bequeathed about $2,500 to the *Centralverein deutscher Zahnaerzte*, the national association of dentists, to promote the study of stomatology at the German universities.

Scarcity of Psychiatrists in Germany.—Already the cry goes forth that there are not enough young psychiatrists to supply the demand in the German asylums. In order to attract young physicians to this branch of medicine the salaries and perquisites are being increased in some parts of Germany. They already range rather above the average, we understand.

Subjects of Berlin Prize Essays.—The subject announced by the medical faculty at Berlin for the essays in competition for the royal prize is: "Comparative Research on the Histogenesis of the Heart Musculature to Determine Specially Whether the Muscular Tissue Represents Syncytium or Belongs to the Cell Domain." The subject for the city prize essay is: "Research on the Normal and the Pathologic Anatomy of the Appendix."

Kahlbaum Endowment.—The mother of the late professor of chemistry at Basle, George W. A. Kahlbaum, has presented $9,500 to the national society for the study of the history of medicine (*Deutsche Ges. f. Geschichte der Med. u. Naturwissenschaften*), which was recently founded by her deceased son She has also given the Berlin branch of the same society $5,000, the total of the Kahlbaum endowment thus amounting to nearly $15,000.

German Naturforscher Society.—The German Association of Physicians and Scientists, better known as the "Naturforscher Association" or *Gesellschaft deutscher Naturforscher und Aerzte*, was organized for the advancement of science in all its branches. It now numbers 2,800 members and has had several bequests and endowments and frequently has a surplus left from its largely attended annual meetings. Its total capital is now about $51,000. The seventy-eighth annual meeting is to be held this year at Stuttgart, September 16 to 22. The sections for medicine and surgery form an important gathering of physicians and surgeons from all over the German-speaking countries.

Prizes Offered by Brazilian Academia Nacional de Medicina.—Among the subjects for essays to be offered in competition for the prizes are "Heat Fevers in Rio de Janeiro;" "Influence of Malaria as Determining Factor in Aortic Affections;" "Normal Stature of Children Under 2 at Rio;" "Ideal Treatment of Aneurisms;" "Etiologic Rôle of Popular Diet in Rio;" "Surgical Treatment of Tuberculous Joint Affections;" "Comparative Frequency of Syphilis and Tuberculosis in Children in Rio;" "Indications and Contraindications for Obstetric Intervention;" "Study of the Mineral Waters of Brazil;" and "Study of the Native Plants that Induce Paralysis or Convulsions." The prizes consist of gold and silver medals, but the Alvarenga prize of about $60 and the Dos Santos prize of about $50 will be given respectively for the best work in any branch of medicine and the best medical study of a Brazilian plant.

Prophylaxis of Cancer and Venereal Disease.—Prof. J. Dollinger is distributing a circular warning of the danger of cancer and the benefits of early operation, giving the circular to all the inmates of his surgical service. The circular states the early signs of cancer, and urges every one to apply to a physisician for examination when there is long-continued hoarseness or difficulty in swallowing, or symptoms attract attention to the stomach, or a bunch can be palpated in the abdomen, breast or elsewhere, or there is pain in defecation or the stools or urine are blood stained, or there is a discharge from the genitals at an unusual time. Professor von Bokay urges diligent collecting of statistics and of all facts bearing on cancer as a preliminary to the next international medical congress which is to be held at Budapest in 1909, as already announced. When data have been collected he hopes for a successful national cancer congress to collate and discuss the question of cancer exclusively before the international congress. A letter from Budapest in the *Med. Klinik* for August 12 adds to the above statements that the National League for the Repression of Venereal Diseases has appealed to the medical inspectors of the schools to enlighten youth in the first year or so in college in regard to the dangers of sexual intercourse. The directors of the high schools and colleges are urged to have the customary closing banquet a mid-day instead of a night function.

Non-use of Tuberculosis Sanatoriums in France and Belgium.—A large and supposedly model sanatorium for the tuberculous poor was erected in France three or four years ago and one in Belgium. Our French and Belgian exchanges are now commenting on the fact that these sanatoriums are practically empty all the time, with scarcely a dozen inmates to take advantage of the accommodations freely offered. The reason for this is stated in a Belgian exchange to be the fact that the sick wage-earner, as long as he is able to be about, continues at work to keep his family from starving. He does not give up and go to a sanatorium until he has reached the end of his forces, and then it is usually too late for chance of recovery. The public sanatoriums in France and Belgium lack the basis on which they have flourished to such an extent in Germany, that is, the compulsory insurance against sickness enforced for wage-earners. These sickness insurance companies are on the alert to detect tuberculosis in its incipiency, and those affected are obliged to take a serious course of treatment, generally in a sanatorium, while the indemnity paid insures the support of the family left at home. The article in question states that lacking this fundamental and beneficent legislation, the sanatoriums and convalescent homes in Belgium will continue to remain empty. It adds that the sickness insurance companies in Germany make large profits out of the business while the morbidity of the populace is being notably reduced, the working capacity increased, and distress from poverty due to sickness of the breadwinner has enormously diminished. A Belgian capitalist bequeathed a million dollars five years ago to erect a sanatorium for women, but the authorities are postponing its construction until signs indicate that it is needed.

LONDON LETTER.

(From Our Regular Correspondent.)

London, Aug. 18, 1906.

Drastic Bill to Prevent Juvenile Smoking.

A select committee of the house of lords has adopted a drastic bill to prevent juvenile smoking. Its most striking provisions are as follows: "Every child under the age of 16 who shall be found in the possession of cigarettes or smoking tobacco in any form shall on conviction be liable to a penalty of not exceeding 40 shillings for each offense and shall be subject to the provisions of the Youthful Offenders' Act, 1901. Every person who knowingly sells or suffers to be sold or delivered any description of cigarettes to any child under the age of 16 years shall be liable to a penalty not exceeding 40 shillings for the first offense and not exceeding 5 pounds for every subsequent offense." The committee recommend that police constables shall be empowered to stop all youths apparently under the age of 16 seen smoking in any public place and allowed to confiscate any tobacco found on them. In making this report the committee were much impressed by the unanimous opinion of all the witnesses, including representatives of the tobacco trade, that "the habit of juvenile smoking produces indirectly a number of ills, facilitates the work of disease and leads to habits of drink. They were especially impressed by the evidence to the effect that there are no signs of physical deterioration among girls. The witnesses all said that the reason for this was that girls are, generally speaking, entirely free from this habit." It was proved conclusively that juvenile smoking has increased rapidly of recent years, and it was urged that while its present influence is bad, the effects must be worse in future generations.

The Declining Birth Rate.

The phenomenon of a declining birth rate, which has been noted several times before in The Journal, still continues. The births registered in the second quarter of 1906 were in the proportion of 27.5 annually per 1,000 of the population. This is the lowest birth rate recorded in any second quarter since civil registration was established. The mean rate in the preceding 10 quarters was 29.1. The natural increase in the population of England and Wales during the quarter by excess of births over deaths was 111,800 against 117,850 in the second quarter of 1903, 114,389 in 1904, and 113,726 in 1905. The marriage rate is also declining. During the first quarter of this year it was 10.7 against an average of 11.4 in the first quarters of the preceding 10 years. The death rate shows some improvement. During the second quarter of 1906 it was 14.6 against 15.9 an average of in the preceding 10 years. Infantile mortality was 102 deaths per 1,000 registered births against an average of 119 in the preceding years.

Dyed Meat.

The sale of unwholesome food is by no means confined to Chicago products and the methods of sophistication are endless. A butcher has been summoned for having on his premises 105 pounds of meat intended for the food of man which was unwholesome. Among the articles found were two tins of beef brawn which was the product of a diseased animal. Dr. Bousfield, public analyst, stated that on cutting the meat open he found an abscess cavity from which he took a soft pulpy substance, microscopic examination of which revealed the ordinary bacteria of suppuration. The animal must have suffered from antemortem inflammation. The meat had been colored with an analin dye, producing a salmon tint. A fine of $4 and $50 costs was imposed.

Pharmacology

THE COMPARATIVE PHYSIOLOGIC ACTIVITY OF SOME COMMERCIAL SUPRARENAL PREPARATIONS.

Reid Hunt, M.D.

Chief of Division of Pharmacology, Hygienic Laboratory, United States Public Health and Marine-Hospital Service, Member of the Council on Pharmacy and Chemistry of the American Medical Association.

WASHINGTON, D. C.

The Hygienic Laboratory has recently been requested by another office of the government to compare the physiologic activity of certain suprarenal preparations which had been offered at different prices on competitive bids. After a consideration of various methods proposed for standardizing such preparations (colorimetric methods by Abel, Batelli and others; effect on the pupil of the frog's eye as recommended by Ehrmann, etc.), it seemed that the blood-pressure method was the most suitable for my purposes, especially as the question to be answered referred more to relative than to absolute strength. By observing certain simple precautions it is possible to obtain very uniform results by the blood-pressure method. The most important of these precautions is to have the animal in such a condition that as few factors as possible are to be considered. The animal should be thoroughly anesthetized, and preferably curarized also, so as to avoid effects on the blood-pressure of any movements or disturbances in respiration resulting either directly from the drug or from changes in the blood pressure. The vagi should be cut or atropin used, so as to exclude the changes in the heart rate due to the direct action of the drug on the cardio-inhibitory apparatus or to the effect of changes of blood pressure on this apparatus. All injections should be made at a uniform rate and into veins as remote from the heart as possible. In the present experiments the injections were invariably made into the saphena veins and the duration of the injection accurately recorded on the kymograph. The various preparations to be compared were injected into the same animal and at intervals of a few minutes of each other; one preparation was injected into the right saphena vein, the other into the left, and the injections were repeated a number of times. The blood pressure was taken from the carotid artery.

FIRST SERIES.

In this series three preparations of the active principle w examined, all purporting to be solutions 1 to 1,000. T price asked for two, A and B, was about 70 cents per ounc for the other, C, 42 cents.

Two bottles of each were purchased on the open market; r difference in strength between the two bottles of the sam preparation was found.

Experiment, April 2.—Rabbit, 2,140 gm.; anesthetized with urethane and chloral hydrate; vagi cut.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
1:49	A, 1 to 25,000..........1 c.c.	105	157	52
1:53	B, 1 to 25,000..........1 c.c.	103	154	51
2:13	C. 1 to 25,000..........1 c.c.	103	140	37

The rise of blood pressure from equal amounts of A and B were practically equal and about 1.4 times as great as that from C.

Experiment, April 6.—Rabbit, 2,250 gm.; urethane and chloral; curare; vagi cut.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
2:02	C, 1 to 25,000..........7 c.c.	90	151	61
2:05	B, 1 to 25,000..........1 c.c.	90	192	102

The rise of pressure from B was nearly 1.7 times as great as that from an equal amount of C.

Later in this experiment the following results were obtained:

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise
3:31	C, 1 to 25,000..........1 c.c.	78	108	30
3:34	B, 1 to 25,000..........1 c.c.	78	132	54

The rise of pressure from B was 1.8 times as great as that from C.

The following results were obtained with C and A:

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
3:59	C, 1 to 25,000..........1 c.c.	80	116	36
4:01	A, 1 to 25,000..........1 c.c.	78	142	64
4:03	C, 1 to 25,000..........1 c.c.	81	124	43
4:10	A, 1 to 25,000..........1 c.c.	79	146	67
4:21	C, 1 to 25,000..........1 c.c.	82	122	40

Thus the rise of blood pressure from A was about 1.6 times as great as that from C.

In the following experiments equal amounts of different dilutions were injected:

Experiment, April 9.—Rabbit, 1,850 gm.: urethane and chloral hydrate; curare; vagi cut.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
3:38	C, 1 to 18,000..........1 c.c.	105	135	30
3:41	A, 1 to 25,000..........1 c.c.	102	138	36
3:55	C, 1 to 11,000..........1 c.c.	73	130	57
3:59	A, 1 to 25,000..........1 c.c.	75	127	52
4:08	A, 1 to 25,000..........1 c.c.	68	123	55
4:11	C, 1 to 15,000..........1 c.c.	70	124	54
4:15	A, 1 to 25,000..........1 c.c.	68	121	53

Thus when the ratio of the strength of C to that of A was about 1.7 to 1, approximately equal rises of blood pressure were obtained from equal amounts of the preparations.

In another experiment the following results were obtained:

Experiment, April 10.—Rabbit, 1,720 gm.: urethane and chloral: curare: atropin.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
3:57	C, 1 to 12,500..........1 c.c.	86	145	59
4:00	A, 1 to 25,000..........1 c.c.	84	144	60
4:13	A, 1 to 100,000..........1 c.c.	82	122	40
4:15	C, 1 to 50,000..........1 c.c.	76	126	50
4:19	A, 1 to 85,000..........1 c.c.	79	127	48
4:23	C, 1 to 50,000..........1 c.c.	75	122	47

Here again in order to obtain equal rises of blood pressure it was necessary to use a solution of C about 1.7 times as concentrated as of A. The rise of pressure in the first two injections was maximal; a weaker solution of each would probably have caused as great an effect.

CONCLUSIONS.

The above experiments show that equal amounts of equal dilutions of A and B have equal effects on blood pressure; (2) that A and B cause from 1.4 to 1.8 times the rise of blood pressure as do equal amounts of C, and (3) that in order to obtain equal rises from equal amounts of C on the one hand and A and B on the other it is necessary to have the solution of the former about 1.7 times as concentrated as of the latter. Hence we may conclude that B and A were of about equal strength and that they were about 1.7 times as active as C. The apparent discrepancy under (2) is readily explained as follows: In those cases in which the rise from A (or B) was about 1.4 times as great as that from C the effect of the former was already maximal and the same effect would have been produced by solutions weaker than the one actually employed.

It is interesting to note that the prices at which these preparations were offered were in direct proportion to their strength; the price asked for A and B was about 1.7 times as great as that of C, and the strength of the former was about 1.7 times as great as that of the latter.

SECOND SERIES.

In this series we were requested to test four preparations, three of solutions of the active principle (labeled 1 to 1,000) and one of the dried and powdered gland. Two of the preparations, C and A, were from the same manufacturers as in the first series. These preparations were offered at the following prices:

	19 cents
D, 25 c.c.	60 cents
A, 25 c.c.	60 cents
C, 25 c.c.	72 cents
Suprarenal gland (desiccated), 1 ounce	

The samples were submitted by the competing firms.

The examination was made as in the first series. Inasmuch, however, as the most satisfactory results were obtained when equal amounts of different dilutions were compared, only these results will be reported here.

Experiment, June 15.—Rabbit, 2,770 gm.: urethane and chloral hydrate; curare; vagi cut.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
4:13	D, 1 to 50,000..........1 c.c.	65	89	24
4:15	A, 1 to 100,000..........1 c.c.	64	122	58
4:20	D, 1 to 25,000..........1 c.c.	65	100	35
4:23	A, 1 to 100,000..........1 c.c.	58	114	56
4:30	A, 1 to 150,000..........1 c.c.	63	107	44
4:44	A, 1 to 150,000.......... 1 c.c.	69	111	42
4:46	D, 1 to 20,000..........1 c.c.	74	127	53
4:54	A, 1 to 100,000..........1 c.c.	71	125	54
5:01	D, 1 to 20,000..........1 c.c.	70	119	49
5:07	C, 1 to 100,000..........1 c.c.	77	120	43
5:11	A, 1 to 100,000..........1 c.c.	82	130	48
5:37	D, 1 to 20,000..........1 c.c.	90	120	30
5:41	C, 1 to 100,000..........1 c.c.	90	117	27

An examination of the above table shows that approximately equal rises of blood pressure from A and D were obtained only when the concentration of the latter was about five times as great as that of the former. The figures are not so satisfactory for comparing the strengths of A and C, but they indicate in a general way that these preparations were of nearly equal strengths.

Experiment, June 21.—Rabbit: urethane and chloral hydrate; curare; vagi cut.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
3:25	D, 1 to 10,000..........1 c.c.	62	120	58
3:35	A, 1 to 50,000..........1 c.c.	62	121	59
3:38	D, 1 to 20,000..........1 c.c.	67	112	45
3:49	A, 1 to 100,000..........1 c.c.	56	102	46
3:51	D, 1 to 40,000..........1 c.c.	64	85	21
3:56	A, 1 to 150,000..........1 c.c.	62	96	34

These results show again that equal rises of blood pressure were obtained only when D was about five times as concentrated as A.

Similar results were obtained later in the same experiment; as shown in the following table, the effect on the blood pressure was less, but the two preparations had the same relative activity. These figures also show that C and A were of about the same strength and also give approximate results for the relative strengths *of decoctions of the dried glands and the* active principle.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
4:40	Suprarenal gland, 1 to 1,000..1 c.c.	52	97	45
4:46	Suprarenal gland, 1 to 2,000..1 c.c.	49	72	23
4:50	A...............1 to 100,000..1 c.c.	48	70	22
4:53	C...............1 to 100,000..1 c.c.	45	68	23
4:58	D...............1 to 20,000..1 c.c.	43	68	25
5:01	D...............1 to 40,000..1 c.c.	43	54	11
5:04	C...............1 to 100,000..1 c.c.	40	60	20
5:14	Suprarenal gland, 1 to 500..1 c.c.	38	80	42
5:21	A...............1 to 50,000..1 c.c.	47	91	44
5:27	D...............1 to 10,000..1 c.c.	40	83	43
5:30	D...............1 to 20,000..1 c.c.	43	66	23
5:33	A...............1 to 100,000..1 c.c.	42	62	20
5:36	Suprarenal gland, 1 to 250..1 c.c.	27	106	79

For some reason the results of these experiments with decoctions of the dried gland (made by warming on the water bath for one-half hour with *normal saline solution*) are not very concordant. Thus in the first injections (4:46 and 4:50)

1 c.c. of a decoction of the gland 1 to 2,000 caused a rise of blood pressure equal to that caused by 1 c.c. of A 1 to 100,000; this would indicate that 1 gm. of the dried gland would yield 20 c.c. of a decoction equal to A 1 to 1,000. In the later injections, however (5:14 and 5:21), 1 c.c. of a decoction of the gland 1 to 500 caused a rise of blood pressure equal to that caused by 1 c.c. of A 1 to 50,000; or, according to these results, 1 gm. of the dried gland would yield but 10 c.c. of a solution corresponding to a solution 1 to 1,000 of the active principle.

Special attention was given to the determination of the relative strengths of decoctions from the gland and A in the following:

Experiment, July 6.—Rabbit, 1,750 gm.; urethane and chloral hydrate; curare; vagi cut.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
4:27	A...............1 to 50,000..1 c.c.	56	90	34
4:35	Suprarenal gland, 1 to 750..1 c.c.	60	95	35
4:47	A...............1 to 50,000..1 c.c.	64	98	34
4.52	Suprarenal gland, 1 to 750..1 c.c.	65	96	31
5:03	A...............1 to 100,000..1 c.c.	45	70	25
5·05	Suprarenal gland, 1 to 1,125..1 c.c.	50	75	25
5:12	Suprarenal gland, 1 to 1,500..1 c.c.	38	57	19
5:15	A...............1 to 100,000..1 c.c.	36	54	18
5:35	A...............1 to 25,000..1 c.c.	45	105	60
5:39	Suprarenal gland, 1 to 750..1 c.c.	50	101	51

The results again are not entirely concordant, but they show that 1 gm. of the dried gland yielded from 11 to 15 c.c. of a solution corresponding to a 1 to 1,000 solution of the active principle (1 gm. of the gland macerated with 750 c.c. normal saline yielded a solution, 1 c.c. of which equaled, physiologically, 1 c.c. of A 1 to 50,000; or 50 c.c. of the gland decoction, 1 to 750, would equal, physiologically, 1 c.c. of a solution of A 1 to 1,000. Hence 750 c.c., the decoction prepared from 1 gm. of the gland, equaled, physiologically, 15 c.c. of A 1 to 1,000).

Three days later the same solutions were again tested; the results were similar, but indicated that the decoction from the gland had undergone greater deterioration than had the solution of the active principle.

Experiment, July 9.—Rabbit, 2,090 gm.; urethane and chloral hydrate; curare; vagi cut.

Time.	Preparation.	Blood-pressure in mm. of mercury.		
		Before.	After.	Rise.
1:43	Suprarenal gland, 1 to 1,875..1 c.c.	42	64	22
1:46	A...............1 to 125,000..1 c.c.	40	68	28
1:53	A...............1 to 100,000..1 c.c.	38	70	32
1:55	Suprarenal gland, 1 to 150,000..1 c.c.	38	64	26
1:57	A...............1 to 100,000..1 c.c.	37	65	28
2:09	A...............1 to 50,000..1 c.c.	40	100	60
2:10	Suprarenal gland, 1 to 750..1 c.c.	42	90	48
2:13	A...............1 to 50,000..1 c.c.	38	98	60
2.20	A...............1 to 75,000..1 c.c.	36	70	34
2:24	Suprarenal gland, 1 to 1,050..1 c.c.	40	76	36
2:26	A...............1 to 75,000..1 c.c.	37	74	37

CONCLUSIONS.

From these experiments we may conclude that the samples of C and A were of about equal strength and approximately five times as strong as the sample of D. Although the price at which the latter was offered was but approximately one-third of that of the former, it was in reality the most expensive of the three. These experiments also show that the physician or pharmacist could prepare from an ounce of dried suprarenal gland about 15 fluid ounces of a decoction equal in strength to that of the active principle 1 to 1,000. As the price of an ounce of the dried gland is but little higher than that of a fluid ounce of the solution 1 to 1,000, the economy of using the former, when practicable, is evident; in practice there are, however, many cases in which a solution of the active principle is much to be preferred.

It is interesting to compare the deductions based on physiologic experiments as to the amount of active principle present in the dried gland with the chemical results. Abel (*American Journal of Pharmacy*, 1903, p. 312) calculated that the fresh beeves' suprarenals contain at least 0.3 per cent. of the active principle. One part of the dried gland corresponds, according to the United States Pharmacopeia, to approximately six parts of the fresh gland; hence, according to Abel's experience, the dried gland should contain about 1.8 per cent., or 1 gm. of the dried gland would contain 0.018 gm. of the active principle. Hence 1 gm. of the dried gland should yield about 18 c.c. of a solution corresponding to 1 to 1.000 of the active principle. As a matter of fact, I found that it yielded about 15 c.c. of such a solution, and it is improbable that the gland was completely exhausted in my experiments.

It would not be fair to infer from these experiments that manufacturers are intentionally mislabeling their preparations; it is much more probable that they do not always make their solutions from pure preparations of the active principle, and that afterward the solutions are not tested physiologically with sufficient care. Only one bottle of D was examined, the one submitted by the manufacturers; this, which was so deficient in strength, was stated to have been tested physiologically. It is possible that the solution in this bottle had deteriorated, although it presented none of the ordinary indications of deterioration (turbidity, change in color, etc.). The experiments do, however, show very plainly that some manufacturers do not put out preparations of uniform strength.

THE COMPARATIVE PHYSIOLOGIC ACTIVITY OF SOME COMMERCIAL SUPRARENAL PREPARATIONS.

Pharmacologic Laboratory of Western Reserve University,
Cleveland, Ohio, Aug. 2, 1906.

To the Council on Pharmacy and Chemistry of the American Medical Association:—We submit herewith the following report on the examination of a series of suprarenal preparations, undertaken at your request:

SAMPLES.

The experiments were made with two sets of freshly bought samples, one set (*a*) purchased from a jobbing druggist, the second (*b*) from a high-class prescription pharmacy.

The packages bore the following manufacturers' numbers:

	(*a*.)	(*b*.)
Preparation 1........	C. P. 60183 C. D.	C. P. 60183 C. C.
Preparation 2..........	1083641	1088731
Preparation 3..........	210072	303082
Preparation 4..........	670028	670000

The samples were of acid reaction, except preparation 4, *b*, which was distinctly alkaline and which bore an odor of thymol, absent in sample *a*.

METHODS.

The efficiency was tested by injecting a 1 to 50 dilution (in normal saline) of the 1 to 1,000 solution, usually in doses of 0.5 c.c. per kg. of body weight (equals 0.01 c.c. per kg. of the 1 to 1,000 solution) into the femoral vein of anesthetized dogs, alternating the samples in irregular sequence and taking carotid blood-pressure tracings. The vagi were intact in some, divided in other experiments. In all, seventy-one injections were made on twelve dogs.

The keeping quality was estimated by allowing the above dilutions to stand the specified time and observing the physiologic efficiency and the change of color.

To prevent any possibility of bias, the solutions were made by an assistant and provided with numbers, the identity of the products being unknown to us until the experiments were completed and the conclusions drawn.

RESULTS.

Efficiency of the Fresh Solutions.—Designating the efficiency of the solution of preparation 2, *a*, as 100, that of the other samples of the series is approximately as follows:

	Efficiency of *a*.	Efficiency of *b*.
Preparation 1....................	70	76
Preparation 2....................	100	86
Preparation 3....................	86	63
Preparation 4....................	95	nil.

Suprarenalin, *b*, had no effect on blood pressure, even in doses of 0.1 c.c. per kg., i. e. in ten times the standard dose.

Keeping Qualities of the Diluted Solutions.—This may be judged from the following table:

	Efficiency of Fresh Dilution.	After Standing One Day.	After Two Days	Discoloration in One Day.	In Two Days.
Preparation 1, *a*	70	25	0	None . . .	—
Preparation 1, *b*	70	Active . .	Active . .	None	None.
Preparation 2, *a*	100	0	—	Dark pink.	—
Preparation 2, *b*	86	0	—	Dark pink.	—
Preparation 3, *a*	86	15	0	None . . .	—
Preparation 3, *b*	63	0	—	None . . .	None.
Preparation 4, *a*	95	0	—	Light pink	—
Preparation 4, *b*	0	—	—	Light pink	—

CONCLUSIONS.

In view of the variability in the commercial samples, as revealed in our examination, definite conclusions concerning the comparative activity of the different makes of suprarenal solutions are not warranted. Theoretically, all samples of "1 to 1,000 solution of suprarenal alkaloid" should be of identical strength, just as are all 1 to 1,000 solutions of strychnin. It is evident that this is not the case in practice, and that the physician, in injecting this powerful substance, is at present unable to use a perfectly exact dosage. Our samples of preparations 1 and 2 exhibited less variation than preparations 3 and 4, but we can not be certain that a larger series of samples might not have shifted the relative position. This is also true of the average efficiency, which decreases in the first series of samples from preparation 1 (100) to preparation 4 (95), to preparation 3 (86), to preparation 1 (70); in the second series, from preparation 2 (86), to preparation 1 (70), to preparation 3 ((63), to preparation 4 (0). We repeat that we would not lay any emphasis on the comparative efficiency of the different makes on account of the variability.

The results as to the stability of the solutions are more constant. Preparation 1 is the most stable, then comes preparation 3, then preparation 4, then preparation 2. This subject of stability, however, has probably little practical importance, since the dilutions of all the samples are practically worthless after twenty-four hours.

We are unable to state whether the samples vary in strength when they leave the makers' hands, or whether the differences are due to subsequent deterioration. The former would be quite inexcusable. The latter would seem to demand a dating and returning system similar to that in vogue for antitoxic sera.

Respectfully submitted,
Torald Sollmann,
Edgar D. Brown.

Correspondence

Cocain in Tucker Asthma Cure.

Shiloh, O., Aug. 28, 1906.

To the Editor:—Referring to the article of Dr. Vickery on "Cocain in Tucker Asthma Cure" in The Journal A. M. A., Aug. 4, 1906, I wish to thank the author for his report and to commend his suggestion as to what ought to be done to suppress such a "cure." I had a case here, with all the symptoms of acute cocain poisoning, as the result of using the above preparation. The patient was a child 5 years of age, and I can assure you that a "remedy" that will produce as marked symptoms of poisoning in as short a time as does the Tucker Asthma Cure, needs to be removed from the market, or at least labeled as to its contents, and not retailed to an unsuspecting public as a harmless asthma cure.

N. P. McGay.

The Teaching of Medical Jurisprudence in New York.

Jersey City, Aug. 28, 1906.

To the Editor:—In The Journal, Aug. 25, 1906, page 586, you make the editorial statement that "The New York schools, Columbia, Bellevue and Cornell, make no mention of the subject whatever. Medical jurisprudence is not among the courses required by the New York Board of Regents." I call attention to the fact that Hon. Millard Bartlett of the appellate division of the Supreme Court delivers fifteen lectures each year at the Long Island College Hospital to the third year class.

Walter T. Dannreuther, M.D.

Hay Fever and Ivy Poisoning.

Cincinnati, Aug. 28, 1906.

To the Editor:—A year ago, while suffering from hay fever, I was poisoned with ivy. Though in the midst of the season the hay fever disappeared immediately on the advent of the ivy poisoning and gave me no further trouble that year. Was this a coincidence or a consequence? If the latter, why? Have any more of your numerous readers made the same observation?

Pollantin in hay fever has given me no relief.

E. S. McKee.

Records of Graduates of Flint Medical College.

New Orleans, Aug. 27, 1906.

To the Editor:—At the May meeting of the Louisiana State Board seven of the eight 1906 graduates of Flint Medical College presented themselves for examination, and only one failed to pass. This gives a 14 2/7 per cent. of failures and should place us in Table J of your statistics instead of Table K. In justice to our school and its present administration, may I ask you to publish this statement?

A. D. Bush, Dean.

[Editor's Note.—Tables J and K, to which Dr. Bush refers, appear in the annual Educational Number of The Journal, August 25, and are a part of the detailed summaries of the results of the state board examinations in all states for the year 1905. This May examination, at which he says a better record was made, is, of course, a portion of the record for 1906, and this will be included in a summary of the year 1906 to appear early in 1907.]

Population of Los Angeles.

Los Angeles, Cal., Aug. 27, 1906.

To the Editor:—On page 613 of the Educational Number (August 25) of The Journal, under the California heading, the city of Los Angeles is given a population of 116,420.

Since clinical facilities are dependent somewhat on the amount of population, a correction is in order if a proper impression is to be given. The population of Los Angeles at the present time is over 240,000 instead of 116,420. I refer you to the enclosed article from to-day's Los Angeles *Times* showing the most recent figures. The school census last spring showed a population of 230,000. Further, the city water department has 50,977 service pipes in use and five persons to a service pipe is a conservative average. The monthly health reports are based on a population of 200,000, in order to allow a safe margin, but this estimate will shortly be increased.

Los Angeles then is not in the 100,000 but rather in the 250,000 class, and has clinical facilities commensurate with a city of that size.

George H. Kress.

[Editor's Note:—We are very glad to have this information. As stated in the Educational Number, the figures used were the estimates of the government's Census Bureau for 1903.]

Treatment of Hay Fever by Securing Normal Nostrils.

Hartford, Conn., Aug. 20, 1906.

To the Editor:—In The Journal, August 18, Dr. Dunbar Roy writes that at the session of the Association held at Atlantic City in 1904 I claimed to cure hay fever "by simply forcing patients to become absolute nose breathers." Dr. Roy is in error. I did and do claim to cure hay fever by giving my patients nostrils as nearly normal as possible, and then insisting that they breathe through the nose as Nature intended they should. The perusal of my monograph, "Mouth Breathing," should make clear to the reader what I consider necessary in a general way, not only for the relief but cure of the hay-fever patient, also what I consider harmful to that patient. I have yet to find a hay-fever patient at any period with normal nostrils, although I often find them with nothing more abnormal than a few irritable areas. I have yet to hear of a single patient whom I have discharged—and they are many—who has had a recurrence.

In my opinion a nostril is not normal if it is capable of establishing a contact area, especially below its median line; further, a nostril is not normal which contains a single irritable area. If I can find a contact area in the nostril of a hay-fever patient, at any other period than his hay-fever period, for the purpose of diagnosis, or if that patient reports to me when he has a "cold in his head," that I may observe where his areas of. contact are, I obliterate them when quiescent, either surgically or through cauterization. If I examine the patient during his periodic attack for the first time I advise immediate operation when necessary. I remove what I consider necessary at any point in any nostril, and this without the slightest fear of establishing atrophic areas, since I know my patient is going to become a normal breather. I fully appreciate that indiscriminate cutting would prove disastrous, but if we use a little common sense, backed by experience and some originality, and depend less on the general run of text-books whose authors copy one from another treatment that a school boy with a rudimentary knowledge of physiology should deem absurd, oft-times treatment handed down for generations, we will prove ourselves worthy of the respect of the general public.

We will accomplish much if, instead of waiting for immunizing serums to do the work for us which we are too lazy to do ourselves, we awaken to the fact that Nature stands willing to furnish us a power to resist not only hay fever, but all other affections of the breathing tract when once the upper breathing tract is as nearly normal as possible.

Dr. Roy further states: "After a thorough trial of this method, with the hearty coöperation of my patients, I have not been able to secure the results claimed by Dr. Fitzgerald." My advice to Dr. Roy, whom I believe to be a conscientious and painstaking rhinologist, is to become more familiar with my method, and then to give it a thorough trial to prove to his own satisfaction that we have found "the light which will lead us out of the darkness and gloom" for which he writes he is waiting. W. H. Fitzgerald.

Treatment of Hay Fever by Dunbar's Remedies (Pollantin).

La Junta, Colo., Aug. 22, 1906.

To the Editor:—I have read with interest the reports made through The Journal on the use of pollantin in hay fever. My experience has been very limited; I have never used it until within the last two months. Four cases treated resulted as follows:

1. A very aggravated case, in an aged person, who every year suffers intensely. The relief from the eye symptoms was immediate. For the nasal symptoms, which were but slightly relieved, a weak solution of adrenalin was ordered (this previously had given to this patient relief for a few moments only) to be followed by the pollantin. Relief was very marked and three weeks later patient reported herself as being more comfortable than she had ever dared hope to be.
2. First attack, in a person who has resided here several years. Eye symptoms predominated. Relief was very rapid. This may not have been a true case of hay fever.
3. This man suffers severely every season with well-marked symptoms. He thought that he got a little relief.
4. Patient two years from the East, who never had an attack while here. Hay fever came in the first year of his residence here. No relief.

In these cases no attempt was made to treat any abnormal systemic conditions, nor were the proprietor's directions as to sleeping with closed windows, etc., followed. The preparation used was the powder, and the fall variety. The originators are fairly conservative in their claims as set forth in the literature, but the way in which the preparation is marketed will soon put it out of the hands of physicians and into the hands of the laity. E. Gard Edwards, M.D.

Book Notices

Eczema. A Consideration of Its Course, Diagnosis and Treatment Embracing Many Points of Practical Importance, and Containing 146 Prescriptions, Illustrating Dosage in Local Applications. By Samuel H. Brown, M.D., Assistant Dermatologist, Philadelphia Hospital, etc. Cloth. Pp. 105. Price, $1.00. Philadelphia: P. Blakiston's Son & Co., 1906.

In the first 28 pages the author considers briefly the varieties, etiology, pathology, symptoms and diagnosis of this disease. The other 71 pages are devoted to treatment. Instead of generalizing, the author gives prescriptions for both local and general treatment.

Military Hygiene. By Robert Caldwell, F.R.C.S., D.P.H., Lieutenant-Colonel Royal Army Medical Corps; formerly Medical Officer in Charge District Laboratory, Meerit; Member of Committee on Field Sanitation in Connection with Surgeon-General's Report on South African Campaign; Medical Officer in Charge, District Laboratory and Isolation Hospital, First Army Corps. New York: William Wood & Co. 1905.

The object of the book, as the author states, is to give "a short account of those principles of sanitation which most nearly affect the soldier in his every-day life." Of course, it does not go so deeply into details as the encyclopedic work of Munson, but it is in the main accurate, and the advice given will prove valuable both to the junior and senior officers. The author seems to be a little too conservative in certain matters, such as that of the use of kerosene in marshes, the employment of mosquito nettings, the practicability of sterilization of water by boiling, etc.

The Ophthalmoscope and How to Use It. With Colored Illustrations. Descriptions and Treatment of the Principal Diseases of the Fundus. By J. Thorington, A.M., M.D. 13 Illustrations and 12 Colored Plates. Cloth. Pp. 298. Price, $2.50. Philadelphia: P. Blakiston's Son & Co., 1906.

This may be described as a condensed text-book. While avoiding long mathematical calculations, it leaves little to desire in the matter of clearness of text or illustration. The ten chapters treat of the ophthalmoscope, optics, anatomy and anomalies of the eye, the normal eye ground, structural changes in disease, the vision, retinal vessels, diseases of the retina, of the optic nerve, and of the choroid. Besides numerous figures in the text, it contains twelve excellent colored plates of the fundus in health and in a variety of diseases of the retina and other structures.

A Text-Book of Human Physiology, Including a Section on Physiologic Apparatus. By A. P. Brubaker, A.M., M.D. Second Edition. Revised and Enlarged, with Colored Plates and 356 Illustrations. Cloth. Pp. 715. Price, $4.00. Philadelphia: P. Blakiston's Sons & Co., 1905.

The second edition of this work is improved by thorough revision of the sections on the chemistry of the proteids, the chemistry of digestion, the movements of the intestines, the production of lymph, the nerve mechanism of the heart, and the physiology of vision. In the section on the movements of the intestines the author refers to the investigations by Cannon by means of the Roentgen rays and the fluoroscope. Of the production of lymph from the blood and its diffusion he admits that the last word has not been said. The present edition reflects fairly the present state of knowledge and commends itself to all who are interested in the subject, whether as teachers, students or practitioners.

Deaths

Charles G. Bacon, M.D. Albany (N. Y.) Medical College, 1874, who attended a course of lectures in that institution in 1840-1841 and in March, 1841, was licensed to practice in the state of New York by the New York State Medical Society; for 45 years a practitioner of Fulton, N. Y.; a member of the Oswego County Medical Society and a delegate in 1854 to the American Medical Association; for 15 years a censor of the New York State Medical Society; in 1843 hospital brigade surgeon for the Forty-eighth brigade of the Militia of the State of New York, with the rank of major; given an honorary medical degree by the regents of the State of New York in 1858; in 1887 president of the New York Central Medical Society, died at his home in Fulton, August 18, aged 92.

William Edwin Taylor, M.D. Medical College of the Valley of Virginia, Winchester, 1859; medical inspector United States Navy, retired; who was appointed to the Navy in 1859 and served 10 years and 5 months on sea duty and 12 years and 3 months on shore and other duty, until his retirement on account of ill health in 1881; for 18 years professor of surgery in the Medical Department of the University of California, and during that time president of the Medical Association of the City and County of San Francisco; since 1898 a resident of Honolulu, H. I., where he served as president of the local medical society and as a member of the Board of Medical Examiners and of the Board of Dental Examiners of the territory, died at his home in Honolulu, July 30, aged 68.

James W. Breedlove, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1849, of Fort Smith, Ark.; for 12 years surgeon in the United States Marine-Hospital Service at New Orleans; surgeon of the Third Louisiana Infantry and later medical inspector in the Confederate service during the Civil War; a charter member of the Sebastion County (Ark.) Medical Society and at one time its president, died at Belle Point Hospital, Fort Smith, August 16, from paralysis, after an illness of four months, aged 79.

George F. Brendle, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1862; a member of the American Medical Association and a veteran physician of Mahanoy City, Pa.; for many years a member and officer of the Schuylkill County Medical Society; a charter member of the borough of Mahanoy City and councilman and chairman of the sanitary committee of that borough, died at his home, August 23, from heart disease, after a prolonged illness, aged 69.

Robert L. McCurdy, M.D. Cleveland Medical College, Medical Department of Western Reserve College, 1853; said to have been the oldest practitioner of Freeport, Pa.; at various times burgess, councilman and school member of the Freeport board of health; a member of the Medical Society of the State of Pennsylvania, Armstrong County Medical Society and Allegheny Valley Medical Society, died at his home in Freeport, August 26, after a brief illness, aged 81.

William Rockwell Cheever, M.D. College of Physicians and Surgeons of Chicago, 1896; a member of the American Medical Association and Wisconsin State Medical Society; president of the Kenosha Medical Society and treasurer of the Kenosha County Medical Association; one of the most brilliant young physicians of Kenosha, was found dead in his room in that city from accidental asphyxiation by gas, August 30, aged 38.

Richard Coleman Carlisle, M.D. New York University, New York City, 1862; assistant surgeon in the Confederate service and assigned to duty at Chimborazo Hospital, Richmond, and later surgeon of the Seventh South Carolina Infantry; a prominent citizen of Newberry County, S. C., died at his home nine miles north of Newberry, August 21, from acute gastritis, after an illness of one week, aged 70.

William H. McCullough, M.D. Cincinnati College of Medicine and Surgery, 1878; of Tarentum, Pa.; formerly burgess of Tarentum and member of the legislature from the Seventh district; superintendent of the Sandusky County Home, Woodvile, Ohio, in 1900, died at the home of his sister, in Petrolia, Pa., August 25, after a prolonged illness, from injuries received in a railroad accident, aged 55.

John N. Bassett, M.D. New York University, New York City, 1882; a member of the American Medical Association; once president of Canton, N. Y., and for 12 years a member of the school board; one of the most esteemed practitioners of St. Lawrence County, died at his home in Canton, N. Y., August 16, after an illness of two days from cerebral hemorrhage, aged 56.

Jerome B. Greene (Examination. Pennsylvania, 1861); surgeon in the Army throughout the Civil War; for many years a practitioner of Providence, R. I., died suddenly, July 27, from cerebral hemorrhage, while making an address at a reunion of the Rhode Island Fifth Heavy Artillery, aged 75.

John Harris Westerfield, M.D. University of Louisville, Medical Department, 1871, a member of the Polk County (Ark.) Medical Society and of the American Medical Association, died at his home in Atkins, Ark., July 31, from gallstone disease, after an illness of four weeks.

Nathaniel Cass, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1882, several times an alderman of Cameron, Texas, died at his home in that city, August 20, from pneumonia, following an attack of appendicitis, for which operation was performed 25 days before.

Walter Ross Langdon, M.D. Jefferson Medical College, Philadelphia, 1852; of Stockton, Cal.; surgeon in the Confederate Army throughout the Civil War; physician at the Stockton State Hospital from 1871 to 1888, died from heart disease, at Santa Cruz, Cal., August 5, aged 75.

Donald A. Link, M.D. Detroit (Mich.) College of Medicine, 1895, of Volinia, Mich., a member of the Michigan State Medical Society and Cass County Medical Society, was accidentally drowned while shooting the rapids of the Moon River, near Ravenhurst, Ont., August 15, aged 40.

Sam Houston Hynds, M.D. Jefferson Medical College, Philadelphia, 1860; a Confederate veteran; for many years a practitioner of Arkansas and Tennessee, died at Parvin, Texas, July 3, from gastritis and hepatitis, after an illness of two months, aged 69.

Christopher Anton Jaeger, M.D. Western College of Homeopathic Medicine, Cleveland, 1864; a veteran of the Civil War; said to be the oldest practitioner of Elgin, Ill., died at the Sherman Hospital, Elgin, August 24, after an illness of one year, aged 79.

George W. Taylor (Years of Practice, Indiana), a surgeon in the Confederate service during the Civil War and for many years a practitioner of Crawfordsville, Ind., died at his home in that city, June 29, from paralysis, after an illness of 11 years, aged 85.

John Gregg (Years of Practice, W. Va.), a veteran of the Civil War and one of the oldest practitioners of Harrison County, W. Va., died in St. Mary's Hospital, Clarksburg, August 18, from nephritis, after an illness of several weeks, aged 68.

Jesse W. Jansen, M.D. New York University, New York City, 1886, supervisor from the Sixth Ward of Binghamton, N. Y., in 1892, died at his home in that city, August 27, from nervous prostration, after an illness of three weeks, aged 45.

Walter Tate Cody, M.D. Rush Medical College, Chicago, 1886, of Detroit, was taken ill at Cobalt, Ont., removed to Toronto General Hospital and died in that institution, August 28, a few hours after an operation for brain tumor, aged 48.

Edward D. Perkins, M.D. University of Georgetown, Medical Department, Washington, D. C., 1895, of Washington, D. C., died at Providence Hospital, in that city, August 24, from peritonitis, after an illness of five days, aged 41.

John C. Holmes, M.D. College of Physicians and Surgeons in the City of New York, 1864, a retired practitioner of Cranbury, N. J., was instantly killed by being struck by a train near Jamesburg, N. J., August 21, aged 65.

Walter C. Lohr, M.D. Milwaukee Medical College, 1905, of Denmark, Wis., died at the home of his parents, near West Bend, Wis., August 25, from sarcoma of the breast, after an illness of several months, aged 27.

J. T. H. Scott, M.D. New York Medical College, New York City, 1861; a Confederate veteran; for 40 years a practitioner of Barren Plains, Tenn., died at his home in that place, August 18, from tuberculosis.

Gilbert A. Ewing, M.D. Medical College of Ohio, Cincinnati, 1866, who served as hospital steward during the Civil War, died at his home in Jackson, Ohio, from senile debility, August 19, aged 72.

T. R. Seastrunk, M.D. Medical College of the State of South Carolina, Charleston, 1844, died at his home in Burkeville, Texas, August 20, aged 84.

Joseph E. Couper, M.D. Hahnemann Medical College, Philadelphia, 1881, died at his home in Blue Earth, Minn., August 20, from cerebral hemorrhage, after a brief illness, aged 49.

Edgar F. Bonham, M.D. New York University, New York City, 1883, died suddenly at his home in Fairmount Springs, Pa., August 24, while prescribing for a patient, aged 50.

David H. Bradley, of Mayview, Mo., a member of the Lafayette County Medical Society, died at his home, July 12, from heart disease, after an illness of two years, aged 66.

Jefferson C. Farr, M.D. St. Joseph Hospital Medical College, St. Joseph, Mo., 1878, died at his home in Alanthus, Mo., August 21, after a long illness.

H. Clint Bacon, M.D. Jefferson Medical College, Philadelphia, 1868, died at his home in Harveyville, Pa., August 15, from kidney disease, aged 64.

George W. Burns, M.D. Detroit Medical College, 1868, died at his home in Morrison, Ill., July 3, from nephritis, after an illness of six months, aged 63.

William Anson Bliss, M.D. Albany (N. Y.) Medical College, 1866, died at his home in Brooklyn, N. Y., August 19, after a lingering illness, aged 65.

Beker, M. C., acting asst.-surgeon, to the Naval Hospital, Newport, R. I.

Longabaugh, R. I., acting asst.-surgeon, ordered to Naval Hospital, Mare Island, California.

E. C. Taylor, asst.-surgeon, to the *Hancock*, Navy Yard, New York, N. Y.

J. A. Randall, passed asst.-surgeon, to the Navy Recruiting Station, Denver.

H. L. Brown, asst.-surgeon, detached Navy Yard, Washington, D. C., etc., to the Navy Recruiting Station, Pittsburg, Pa., temporary duty; thence home and wait orders.

N. H. Drake, medical inspector, when discharged treatment Naval Hospital, New York, N. Y., to Washington, D. C., Oct. 1, 1906, examination for retirement, then to home and wait orders.

F. W. S. Dean, asst.-surgeon, detached Navy Recruiting Station, Denver, etc., to Washington, D. C., Sept. 6, 1906, examination for promotion, then await orders.

E. L. Jones, asst.-surgeon, detached Naval Hospital, Mare Island, Cal., Sept. 15, 1906, to duty in attendance on the course of instruction at the U. S. Naval Medical School, Washington, D. C., Sept. 29, 1906.

J. E. Gill, asst.-surgeon, to the Navy Recruiting Station, St. Louis, Sept. 1, 1906, for temporary duty, thence to the Navy Yard, Washington, D. C.

F. A. Asserson, passed asst.-surgeon, to *Columbia*, Sept. 4, 1906.

F. H. Brooks, asst.-surgeon, detached *Columbia*, to the Naval Hospital, Newport, R. I., for treatment.

B. H. Dorsey, asst.-surgeon, to the Navy Recruiting Station, Des Moines, Iowa, Sept. 5, 1906.

E. J. Grow, surgeon, detached *Mohican*, to *Ohio*.

H. E. Odell, passed asst.-surgeon, detached *Galveston*, to *Wisconsin*.

G. M. Olson, asst.-surgeon, detached *Wisconsin*, to *Galveston*.

C. P. Kindleberger, surgeon, detached Naval Station, Olongapo, P. I., to *Baltimore*.

H. G. Beyer, medical inspector, detached *Ohio*, to *Rainbow*.

F. E. Sellers, asst.-surgeon, detached *Ohio*, to *Mohican*.

G. H. Barber, surgeon, detached *Wisconsin*, to the Naval Station, Olongapo.

R. Spear, surgeon, detached *Baltimore*, to the Naval Hospital, Canacap, P. I.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital service for the seven days ending August 29, 1906:

Sawtelle, H. W., surgeon, relieved from duty at San Francisco.

Gassaway, J. M., surgeon, relieved from duty at St. Louis and directed to proceed to Philadelphia, assuming command of the service and relieving Surgeon Fairfax Irwin.

Godfrey, John, surgeon, granted leave of absence for seven days, from Aug. 26, 1906.

Godfrey, John, surgeon, granted an extension of leave of absence for fourteen days from Sept. 2, 1906.

Irwin, Fairfax. relieved from duty at Philadelphia, and directed to proceed to Detroit, assuming command of the service at that port, relieving Passed Asst.-Surgeon Grubbs.

Carmichael, D. A., and Wertenbaker, C. P., surgeons, and Rucker, W. C., asst.-surgeon, detailed to represent the service at the meeting of the Association of Military Surgeons, Buffalo, N. Y., September 11-14, 1906.

White, J. H., surgeon, directed to proceed to Natchez, Miss., for special temporary duty, on completion of which to rejoin his station.

Oakley, J. H., passed asst.-surgeon, granted twenty days' leave of absence, from Aug. 30, 1906.

Grubbs, S. B., passed asst.-surgeon, relieved at Detroit and directed to proceed to St. Louis, assuming command of the service and relieving Surgeon J. M. Gassaway.

Lumsden, L. L., passed asst.-surgeon, leave of absence granted for two months, from June 1, 1906, amended to read one month only.

Corput, G. M., passed asst.-surgeon, granted one month's leave of absence, from Aug. 30, 1906.

McLaughlin, A. J., passed asst.-surgeon, granted leave of absence for one month, from Aug. 15, 1906.

Ward. W. K., asst.-surgeon, granted leave of absence for five days, from Aug. 20, 1906, under paragraph 191 of the Regulations.

Hunt, Reid, chief, division of pharmacology, detailed to attend the meeting of the Council on Pharmacy and Chemistry of the American Medical Association. Indianapolis, Sept. 1, 1906.

Harkin, F. McD., acting asst.-surgeon, granted leave of absence for twelve days, from Aug. 28, 1906.

Marsh, W. H., acting asst.-surgeon, granted leave of absence for nine days from Sept. 8, 1906.

Taylor, A. S., acting asst.-surgeon, granted leave of absence for sixteen days, from Aug. 19, 1906.

Townsend, Wesley, acting asst.-surgeon, granted leave of absence for seven days.

Woods. C. H., pharmacist, granted leave of absence for seven days, under paragraph 210 of the Regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, Public Health and Marine-Hospital Serive, during the week ended August 31, 1906:

SMALLPOX—UNITED STATES.

New York: August 11-18, 1 case.

Texas: Houston, August 11-18, 1 case.

Washington: State, July 1-31, 5 cases; Spokane, August 11-18, 1 case; imported.

China: Niuchwang, July 7, 1 case.

France: Marseilles, July 1-31, 5 deaths.

Gibraltar: August 5 12, 1 case.

Great Britain: Liverpool: August 4-11, 1 death.

India: Bombay, July 17-24, 3 deaths; Calcutta, July 7-14, 3 deaths; Karachi, July 15-22, 4 deaths; Madras, July 14-20, 3 deaths; Rangoon, July 7-14, 3 deaths.

Italy: General, July 26-August 9, 18 cases.

Nicaragua: Bluefields, August 2-9, 1 case.

Russia: Moscow, July 21-August 4, 7 cases, 4 deaths; Odessa, July 28-August 4, 2 cases.

Siberia: Vladivostock, July 5-14, 3 cases, 1 death.

Spain: Barcelona, August 1-10, 11 deaths; Cadiz, July 1-31, 1 case.

YELLOW FEVER.

Cuba: Habana, August 25, 1 case.

Mexico: Merida, August 5-11, 8 cases, 3 deaths; Tierra Blancha, August 5-11, 1 case, 1 death; Vera Cruz, August 21, 1 case.

CHOLERA—INSULAR.

Philippines: Manila, June 30-July 14, 268 cases, 243 deaths; Provinces, July 7-14, 247 cases, 177 deaths.

CHOLERA.

India: Bombay, July 17-24, 97 deaths; Calcutta, July 7-14, 8 deaths; Madras, July 14-20, 9 deaths; Rangoon, June 30-July 7, 1 death.

Straits Settlements: Singapore, May 30-June 12, 2 cases 2 deaths.

PLAGUE.

Australia: Adelaide, July 12, 1 case on steamship *Britania*; Fremantle, June 23-30, 1 case; Sydney, June 23-30, 2 cases 1 death.

Arabia: Djeddah, July 16-22, 11 cases; 11 deaths.

Brazil: Bahia, June 30-July 28, 5 cases, 3 deaths.

China: Amoy, July 24, epidemic.

Greece: Athens, July 21-26, 2 deaths.

India: Bombay, July 17-24, 34 deaths; Calcutta, July 7-14, 10 deaths; Karachi. July 15-22, 17 cases, 16 deaths; Rangoon, June 30-July 14, 319 deaths.

Peru: Lima, July 9, 3 cases; Mollendo, July 9, 4 cases; Palta, July 8, 8 cases: Trujillo ,June 9, 3 cases.

Society Proceedings

COMING MEETINGS.

Med. Soc. of the State of Pennsylvania, Bedford Springs, Sept. 11-13.
Washington State Medical Association, Spokane, Sept. 11-13.
Assn. of Military Surgeons of the U. S., Buffalo, N. Y., Sept. 11-14.
Am. Assn. of Obstetricians and Gynecol., Cincinnati, O., Sept. 20-22.
American Electro-Therapeutic Association, Philadelphia, Sept. 18-20.
Medical Association of District of Columbia, Washington, Oct. 2.
Idaho State Medical Society, Lewiston, Oct. 4-5.
Colorado State Medical Society, Denver, Oct. 9-11.
Delaware State Medical Society, Wilmington, Oct. 9.
Medical Society of Virginia, Charlottesville, Oct. 9-11.
Kentucky State Medical Association. Owensboro, Oct. 10-12.
Vermont State Medical Society, Barre, Oct. 11-12.
American Association of Railway Surgeons, Chicago, Oct. 17-19.

AMERICAN ROENTGEN RAY SOCIETY.

Seventh Annual Meeting, held at Niagara Falls, N. Y., Au 23-30, 1906.

The President, Dr. Henry Hulst, Grand Rapids, Mich., i the Chair.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr. Preston M. Hickey, Detroit; vice-presidents, Dr. Percy Brown, Boston; Dr. S. Cummings, Toronto; Dr. Arthur Holding, Boston; Dr. George E. Pfahler, Philadelphia; Dr. George H. Stover, Denver; secretary, Dr. George C. Johnston, Pittsburg; treasurer, Dr. L. E. Custer, Dayton, Ohio; executive committee, Dr. Joseph F. Smith, Chicago; Dr. F. H. Baetjer, Baltimore; Dr. Kennon Dunham, Cincinnati.

The time and place of the next meeting are to be decided later by the executive committee.

(To be continued.)

BRITISH MEDICAL ASSOCIATION.

Seventy-fourth Annual Meeting, held in Toronto, Ontario, Aug. 21-25, 1906.

(Continued from page 707.)

SECTION ON PSYCHOLOGY.

The session of the Section on Psychology was presided over by Dr. William Julius Mickle of London.

Symposium on General Paresis.

Etiology.—Dr. Allen R. Diefendorf, Middletown, Conn., argued for the greater consideration of other causes in conjunction with syphilis, especially traumata of a mental sort, such as excessive strain, shock, worry, etc. He freely admitted the predisposing influences of syphilis, but said that syphilis alone is not entirely adequate as a cause. In the discussion of the paper the consensus of opinion was that general paresis, in its ultimate etiology, is a product of syphilis.

Symptoms.—Dr. William J. Mickle, London, in introducing the general discussion in the Symposium on General Paresis, read an exhaustive paper covering the symptomatology and pathology with the pathogenesis and prognosis. Acute delirium, in some obscure diseases, is often due to and is associated with general paralysis. So likewise are acute microbic infections and bromids and other intoxications behind the paretic manifestations. Sometimes there is a relationship or at least an association between paranoia and deliria and general paralysis. Four general types of general paresis may therefore be readily recognized. The first includes the degenerates with deliria, but without the physical signs; in the second are the alcoholic and toxic dements; the third represents paranoiac degenerates, while the fourth includes the degenerates that ultimately become demented. In all of these cases dementia is the cardinal manifestation. This gives a broad conception to the term dementia paralytica. Pathologically, the disease is a meningo-encephalitis. There is a double morbid process going on, the one being parenchymatous and degenerative in character, the other interstitial and inflammatory, or at least vascular. Dr. Mickle did not consider the disease so hopeless as many do. Sometimes there is a partial recovery, with only the faintest tracing left of the previous grandiosa ideas. No somatic symptoms remain at all. The individuals go about their work for years as not only harmless but as useful citizens. The author claims that there is recovery from general paresis, because the disease is terminated when there is a separation and disposal of the mental or psychic symptoms. A partial recovery of this sort has been known to continue for thirty or forty years.

The New Psychology.

Dr. Alfred G. Scofield, London, briefly explained the new psychology. He emphasized the existence of the two minds, the conscious and the subconscious or unconscious. Each has its own particular diseases. For example, hysteria, he believes, is disease of the subconscious mind, whereas many of the ordinary mental diseases are affections of the conscious mind.

Staining the Cerebral Nervous System and Relation of Epilepsy to the Central Nervous System.

Dr. John Turner, Brentwood, Essex, presented these two interesting papers, largely illustrated with stereopticon views, showing the cellular changes of the vascular alterations found postmortem in epilepsy.

Cerebral Localization.

Dr. Charles K. Mills, Philadelphia, presented in abstract his paper on "Cerebral Localization in the Study of Psychiatry." After giving a brief historical sketch of his efforts and those of others in this line, the author argued that psychic symptoms, generally in their last analysis—hallucinations, illusions, delusions—are often the result of sensory-cortical disease. Clinical experience and postmortem observations occasionally demonstrate this fact. Psychologic analysis, logic and physiologic data all go to uphold the thesis that mind is the product of brain activity. The brain is a compound, complicated organ, with the working of whose parts (cortical) we are becoming pretty accurately acquainted. The functions of these parts or localizations are easily recognized, singly or in association, as lying behind what we now denominate as psychic manifestations. If this be so, then a disturbance in these psychic manifestations may well be expected to be accounted for on the basis of some cortical brain lesion. This offers a possible physical basis for psychiatry and will remove psychiatry from the plane of a mere functional to that of an organic science. In consonance with this conception of psychiatry, the author detailed a classification of mental diseases different from any hitherto proposed, and based on teratologic and pathologic grounds.

DISCUSSION.

Dr. L. Harrison Mettler, Chicago, in discussing this paper, said that, in general, the position taken by Dr. Mills was incontrovertible. It was an advanced view of psychiatry which would ultimately lead to the abolition of psychiatry as a special department of medicine or the reduction of it to the position of being a part of neurology. The newer physiologic psychiatry has already practically reduced all psychic manifestations to a sensory-motor basis. An idea is the product of the sensory-motor reactions, and all psychoses are the outgrowths ultimately of ideas. If this be so, it follows that the functional interplay of the various sensory-motor centers of the brain, whether in conjunction with, or apart from the inhibitory influence of the prefrontal lobes, underlies the elaboration of what we now call psychic exhibitions. *Per contra,* therefore, any disease or damage of this interplay must necessarily to a greater or less extent provoke an abnormal psychic display. The cortex is not the only sensory-motor basis of mind, for mind is really a mere expression for our reaction to environment. It represents our whole relational life. Sensation and motility underlie its presentations, but sensations and motility are co-extensive with the whole nervous apparatus, and its relationship to the extra-corporeal world, the somatic world and the world of its own physical activities. Hence, mind, is a mere product, not an entity; its diseases are merely symptomatic, and not integral. On this basis, mental diseases are merely exhibitions of the functional reaction of the individual, as shown, preëminently through the nervous system, and as the essayist has shown, the cerebral cortex, particularly in its prefrontal inhibitory workings. It is somewhat along this line that Wernicke worked in his efforts to solve psychiatric phenomena on the basis of known psychologic data in connection with the cortex.

Dr. Charles H. Hughes, St. Louis, said that he had always regarded insanity as a disease, and being a disease as having as physical basis, a lesion of some part, though the nature of this lesion, is usually beyond our present powers of investigation.

Epilepsy.

A general discussion on epilepsy was participated in by Drs. W. Alden Turner, London; W. D. Spiller, Philadelphia; Sanger Brown, Chicago; Charles H. Hughes, St. Louis; William P. Spratling, Sonyea, N. Y., and Charles K. Mills, Philadelphia. There was, of course, the usual diversity of views in certain details, but in the main nothing new was advanced.

Sterilization of Undesirable Denegerates.

Dr. Robert Rentoul, Liverpool, advanced extremely radical views on this subject, and his paper provoked a great deal of discussion. The author proposed that a certain class of defectives, both men and women, should be operated on in such a manner that the sexual desire and the power of sexual intercourse should not be molested, but that the ability to procreate should be destroyed. The feasibility of such an operation is now well established, but its desirability for the purposes proposed was what raised the question. In Dr. Rentoul's opinion it was considered advisable, and in his paper he made arguments for and against the operation. He did not, however, state the exact class of persons on whom it should be performed.

Insanity of Inebriety.

Dr. Thomas D. Crothers, Hartford, Conn., read a paper which provoked considerable discussion, in which he described the various insane manifestations of the inebriate, and ultimately concluded that all alcoholics, whether heavy or moderate drinkers, should be looked on as mentally unbalanced individuals. There may be a question of the degree of mental instability in individuals, but as to the abnormality of their mental state, he said there could hardly be any question. Annually in the United States about 100,000 men die from the direct or the indirect effects of alcohol. The question of the habit is, therefore, a most serious one, both for the individual and for society. The medical profession does not take the interest in this question that it should, and probably because alcoholism and tippling are not strongly enough looked on as a disease. It is a disease, and the victim should be studied and treated as a distinctly diseased individual.

Devolutional Psychoses.

The "Types of the Devolutional Psychoses" were most interestingly elucidated with the aid of a chart by Dr. C. B. Farrar, Baltimore. The paper should be read as a whole and can not be abstracted satisfactorily.

Dementia Præcox.

Dr. Charles Clarke opened the discussion on this subject. The present status of this nosologic entity, if indeed it be such, was outlined. The author presented no definite opinion, but in a very able way gave the history of the rise and adoption of the term, the various meanings assigned to it by different alienists, and the generally unsettled views as to what is exactly meant by dementia præcox. Kraepelin himself had modified his earlier views, and many were still inclined to dissent from him in his later views. Asylum records showed entries of dementia præcox as high as 40 per cent., and yet Kraepelin had stated that of all mental diseases dementia præcox constituted about 15 per cent. Evidently there must be some explanation for this wide discrepancy. The author, however did not make any explanation.

DISCUSSION.

Dr. Adolph Meyer, New York, in the discussion, after showing that a too narrow limitation has been put on Kraepelin's conception of the disease, described, in a most vivid manner, the symptomatology of the cases usually classified under this head. He then elaborated the newer view in psychology that, after all, mental diseases are rather expressions of the individual's reaction to environment, this reaction being largely determined by the preceding heredity and disciplinary influences. In other ways the victim is not the possessor of a nosologic entity, a something added to him, as it were. He is not to be pigeon-holed into this or that mental catalogue of diseases; but, on the contrary, he is born with certain deficiencies and these are, by vicious training or habit, made worse. As a result, he reacts to his environment in a certain way, in consequence of these influences, and this reaction is his psychic exhibition of mental disease. In this sense, dementia præcox is a condition rather than a disease. It is a degenerate reaction of a defective in his surroundings. It varies in degree, from mere indifference all the way up to complete negativism and dangerous outbursts. As a condition, dementia præcox would be better looked on in perspective as a principle at work and reaching back through the individual's past and ancestry, rather than as an assemblage of present rule-of-thumb symptoms. Not its mere termination, nor even its course is of vital importance, but rather the deterioration of habits, the lowering of instincts which it reveals and which etiologically are the outcome of heredity, neuropathic and disciplinary inadequacies. There is no definite histo-pathology of the conditions. We need further data in this respect. All organs, glands and tissues of the body need to be closely studied, even then we may not reach a complete solution. The individual's own mind must be closely observed in its own workings, for the mind can demoralize and undermine itself.

Dr. F. X. Dercum, Philadelphia, said that dementia præcox was admittedly a bad term. It is merely one of expediency, and represents a condition in which the organism as a whole is defective. At first view, it appears to be a functional state leading to some hope of a better outlook, but as time goes on, this hope is usually turned into disappointment. The patient has lost his adjustment to his environment because he was originally defective. The neuropathic histology is important in the etiology of the disease, though infection, nutrition and discipline may all be influential in one way or another in the elaboration of the disease. It is a question for further solution whether the symptoms are functional or structural, inorganic, toxic or organic. It would seem that we are here dealing, at all events, with some altered nutrition or defective metabolism, and consequently with organic degenerative conditions. Kraepelin, like Lister in regard to antisepsis, has performed a stroke of genius in gathering together all of these manifestations of degeneracy of a particular type, putting them into a class, with subclasses, by themselves, and, in general, indicating their prominent characteristics.

Dr. L. Harrison Mettler, Chicago, said that confusion and discrepancies surrounding the term and the conception of Kraepelin's dementia præcox arose from the fact that an effort was being made to name and crystallize into a distinct disease a psychiatric entity which could not be so crystallized or stamped. In his opinion it was a wrong conception of a psychosis, to attempt to make fixed clinical types of certain varied mental manifestations. As Dr. Meyer had indicated, a psychosis is merely the expression of the individual's reaction to his past and present environment. Each individual has his own mode of reaction, depending on a vast complicated mass of hereditary, structural and functional factors. It is the latter we should look to and subject to the closest scrutiny in order to interpret the why and wherefore of the particular individual's psychic manifestations, study each patient *per se*, as Wernicke was wont to do, and account for his exhibitions on the basis of his own history. As had already been stated by those who uphold dementia præcox as a disease, one had to take a perspective view of the disease in every case, had to look back over its progress and not merely at its present symptomatic presentations. The latter have nothing distinctive, and therefore do not portray any distinct disease-entity. Therefore, the upholders of dementia præcox as a disease virtually admit that they diagnosed not a disease but the individual psychic reactions. Dementia præcox is this and nothing more.

Treatment of the Insane.

Dr. E. W. Ryan, Kingston, Ont., presented a very practical paper on "Public and Modern Hospital Methods and the Treatment of the Insane."

Dr. Thomas J. Mohr, Brockville, Ont., read a paper, equally practical in its illustrations, on "Occupation as a Factor in the Treatment of the Insane."

(To be continued.)

AMERICAN ORTHOPEDIC ASSOCIATION.

Twentieth Annual Meeting, held in Toronto, Canada, Aug. 20-22, 1906.

(Continued from page 705.)

Treatment of Spinal Curvature.

Dr. Frank E. Peckham, Providence, R. I., read a paper entitled "The Treatment of Rotary Lateral Curvature of the Spine. Results." For purpose of treatment, the author considers only two factors, notation and rigidity. The greater the rotation and rigidity, the worse the prognosis. All non-symmetrical exercises have been discarded, and the results have improved. The exercises given to any one patient are simple and few, but are performed with great effort at exactness and self-correction, under constant supervision. Each patient must come every day for the exercises, and no exercising is done at home. Three pound dumb-bells and occasionally the elastic exerciser are the only apparatus used. Plaster Paris jackets applied with the patient forcibly corrected by means of thrust-rods in a horizontal frame are occasionally needed in rigid cases, but must be followed by faithful gymnastic work.

Results of Posture.

Dr. Henry O. Feiss, Cleveland, read a paper entitled "Demonstration of Models to Illustrate the Mechanical Tendencies of Posture in the Normal." Model of thorax illustrates: (1) With the segmental motion of the thorax and with the tissue resistance of the lateral walls, distortion will take place in the rib walls if there is any elasticity present; (2), lateral bend has a direct tendency to distort them, and twist has a less direct tendency to do so. Model of vertebra and ribs illustrates: (1) Whatever the tendency for motion is present in the vertebra in nature, it will, if freed, tend to move on its own axis, which is distinct from the axis of motion of the thoracic segment; (2) the vertebral axis will divert from the direction of the median line of the base toward the side on which the curve of the rib prevents the greatest convexity.

Dr. Joel E. Goldthwait, Boston, read a paper entitled, "Anterior Flexion of the Upper Angle of the Scapula as a Cause of Persistent Forward Shoulder, as Well as of Pain and Crepitation in the Scapular Region." Anatomic study of the development of the scapula shows the wide variation of the shape of the upper part. The upper part may acquire a forward bend *due to muscle pull* when the shoulders are held habitually forward. The crepitation is due to the forward-bent upper margin of the scapula sliding over the angles of the ribs, causing a mechanical irritation, and is not due to a bursitis, as formerly supposed. The treatment consists in excising the offending upper margin of the scapula. This stops the pain and crepitation. In women, the incision is made low and the flap dissected up so that the scar shall not show above a low-neck dress.

DISCUSSION.

Dr. Robert W. Lovett, Boston, in discussion of the foregoing papers, said that lateral curvature requires exercise in large doses. The German custom is to require four to six hours daily. Why should American orthopedic surgeons be willing to impair their results through under dosage? It is now needed to apply what we know to what we want to do.

Dr. Compton Riely, Baltimore, said that he had some time ago explained the rib distortion in scoliosis by altered tension of the parietal muscles due to a tilt of the pelvis.

Dr. Reginald H. Sayre, New York, said that lateral curvature produced by forces acting twenty-four hours a day could be overcome only by prolonged application of the correcting means used.

Dr. J. T. Watkins, San Francisco, referred to certain cases of scoliosis which had not improved under exercising until *they were put to bed on curved stretchers in the periods between exercising.*

Dr. Gwilym G. Davis, Philadelphia, said that, as the wound in Dr. Ryerson's case was below the point where it could have done much damage to the nerves supplying the abdominal muscles, the trouble, if due to the muscles at all, must be due to the surgeon's incision.

Dr. Ryerson said that he thought the damage to the muscles in his case was not due to the nerves but to separation of the cut ends of the muscles.

Potts' Disease.

Dr. Compton Riely, Baltimore, said that forward tilting of the pelvis is an important factor in production of the deformity, and it is important to restore it to its normal attitude in preventing and reducing pain, paralysis and deformity. Early diagnosis of Potts' disease in the adult is difficult, and is greatly aided by the x-ray taken in such a way as to show abscess.

DISCUSSION.

Dr. John Ridlon, Chicago, said that Potts' disease in adults is commoner than supposed. He reported two cases.

Dr. Charles F. Painter, Boston, said that the abscesses shown in the radiographs might be due to retroperitoneal glands.

Dr. S. C. Baldwin, Salt Lake City, reported a case of Potts' disease in an adult, with deeply cyanosed legs. The cyanosis was relieved by treatment of the Potts'.

Dr. James K. Young, Philadelphia, reported three cases of Potts' disease in adults, in whom the disease had not been suspected. Unilateral pain is a common symptom in adults.

Dr. Joel E. Goldthwait, Boston, said that aneurism must be considered in diagnosis of these cases.

Dr. Arthur T. Gillette, St. Paul, Minn., reported a case relieved by a jacket, in which autopsy proved the trouble to be aneurism.

Dr. Riely said that he made the diagnosis of Potts' disease on the physical signs as well as on the radiograph.

The Etiology of Juvenile Lateral Deformities of the Spine.

Dr Max Boehm, Boston, said that anatomic study shows frequency of structural asymmetries of the spine, consisting of numerical variations, so-called, that is, the occurrence on one side of a vertebra of characteristics of one vertebral type, and on the other side characteristics of another type. These numerical variations occur usually at the cervicodorsal, dorsolumbar, and lumbosacral junctures, and result in such anomalies as atypical sacral wings and cervical ribs. Such asymmetries can readily account for scoliosis. In twenty clinical cases of scoliosis, examined with special care by the x-ray, numerical variations of the kind to be expected from the kind of curve were found in 85 per cent.

DISCUSSION.

Dr. Arthur H. Freiberg, Cincinnati, said that the specimens of spines with numerical variations were singularly free from curvature. Numerical variations will not account for the progressive character of scoliosis. If a short leg does not produce a progressive scoliosis, why should a slight anatomic variation?

Dr. Gwilym G. Davis, Philadelphia, said that unmercial variations would not account for the great preponderance of the right dorsal convex type of curve.

Dr. Boehm said that the anatomic specimens of spines with extensive numerical variations did show curves. The curve does not come on till puberty because up to that time all the vertebræ are of one type, and the potential variations are therefore not operative till then. This accounts also for the progressiveness of scoliosis, though due to a fixed set of variations. A short leg is less fundamentally disturbing to the spine than numerical variations. Preponderance of the right dorsal convex type is dependent on the tendency of anatomic variations to contract the left side.

Resection of Knee to Obtain a Movable Joint.

Dr. Gwilym G. Davis, Philadelphia, read a preliminary report of a case of apparently bony ankylosis, at 130 degrees, with patella adherent, of three years' standing, following acute rheumatism. Excision was done and a flap of fascia and muscle turned in between raw bone surfaces. Mobility was successfully attained.

The Cause of Straddling Gait in Bow-Legs.

Dr. P. Hoffman, St. Louis, said that children with bow-legs usually walk with the legs and feet widely separated. The common explanation is that this is to maintain equilibrium. The more logical explanation is that it is to allow the lower *parts of the legs to be perpendicular to the ground.* With the feet together, the weight would be on only the outer margins of the feet, or else the feet would be pronated, producing in either case foot-strain.

He also read a paper entitled "The Correct Principle in the Construction of Knock-Knee Braces." The x-ray has shown that the deformity in knock-knee is an inward convexity commonly located at the upper end of the tibia, sometimes at the lower end of the femur, sometimes at both places. The deformity is rarely, if ever, at the knee itself. A brace exerting outward pull or pressure on the knee expends its force mainly when the knee is flexed even only a little in rotating the femur. What directly outward pressure on the knee there is acts largely on the lateral ligaments and tends to produce an unstable joint. The correct brace should exert corrective force directly on the abnormal curve or curves and not on the knee.

Protective Immunization Against Joint Tuberculosis.

Dr. Charles F. Painter, Boston, reported work on immunization by small repeated doses of tuberculin, not more than ¼ mg. at a dose. The work thus far is only preliminary.

DISCUSSION.

Dr. Joel E. Goldthwait, Boston, said that the research conducted by Dr. Painter incidentally showed the nearly constant presence of tubercle bacilli in smears of the pus from cold abscesses. This pus should be as cautiously handled, therefore, and disposed of as tuberculous sputa.

Exceptional Rachitic Distortions of the Legs.

Dr. Wallace Blanchard, Chicago, remarked that skiagraphy shows occasional unusual types of deformities. These should be corrected according to the particular indications. The osteoclasp in all cases should be applied on the external surface of the leg.

(To be continued.)

State Boards of Registration

COMING EXAMINATIONS.

MASSACHUSETTS Board of Registration in Medicine, State House, Boston, September 11-12. Secretary, Edwin B. Harvey, Boston.

IOWA State Board of Medical Examiners, Capitol Building, Des Moines, September 11-13. Secretary, J. F. Kennedy, Des Moines.

OKLAHOMA Board of Medical Examiners, Guthrie, September 25. Secretary, J. W. Baker, Enid.

NEW YORK Boards of Medical Examiners, Albany, September 25-28. Chief of Examining Division, Charles F. Wheelock, Albany.

UTAH State Board of Medical Examiners, Salt Lake City, October 1. Secretary, R. W. Fisher, Salt Lake City.

ARIZONA Board of Medical Examiners, Phoenix, October 1-2. Secretary, Ancil Martin, Phoenix.

COLORADO State Board of Medical Examiners, Denver, October 2. Secretary, S. D. Van Meter, Denver.

IDAHO State Board of Medical Examiners, Lewiston, October 2. Secretary, J. L. Conant, Jr., Genesee.

MONTANA Board of Medical Examiners, Senate Chamber, The Capitol, Helena, October 2. Secretary, Wm. C. Riddell, Helena.

MINNESOTA State Board of Medical Examiners. Old Capitol Building. St. Paul, October 2-4. Secretary, W. S. Fullerton, St. Paul.

NORTH DAKOTA State Board of Medical Examiners, Grand Forks, October 2-4. Secretary, H. M. Wheeler, Grand Forks.

RHODE ISLAND State Board of Health, Room 313, State House, Providence, October 4-5. Secretary, Gardner T. Swarts, Providence.

GEORGIA Board of Medical Examiners (Regular), Capitol, Atlanta, October 9. Secretary, E. R. Anthony. Griffin.

ARKANSAS State Medical Examining Board, Little Rock, October 9. Secretary, J. P. Runyan, Little Rock.

KANSAS State Board of Medical Registration and Examination, State House, Topeka, October 9. Secretary, F. P. Hatfield, Grenola.

MICHIGAN State Board of Registration in Medicine, Lansing, October 9. Secretary, B. D. Harison, Detroit.

MISSISSIPPI State Board of Health, The Capitol, October 9. Secretary, J. F. Hunter, Jackson.

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, October 11. Secretary, Geo. C. Ober, Washington.

NEW JERSEY State Board of Medical Examiners, Trenton, October 16-17. Secretary, J. W. Bennett, Long Branch.

TEXAS State Board of Medical Examiners, Houston, October 16-18. Secretary, T. T. Jackson, San Antonia.

FLORIDA Board of Medical Examiners (Regular), Jacksonville, October 17-18. Secretary, J. D. Fernardez, Jacksonville.

ILLINOIS State Board of Health, Great Northern Hotel, Chicago, October 17-19. Secretary, J. A. Egan, Springfield.

LOUISIANA State Board of Medical Examiners, New Orleans, October 19-20. Secretary, F. A. Larue, New Orleans.

INDIANA Board of Medical Registration and Examination, Indianapolis, October 23-25. Secretary, W. T. Gott, Indianapolis.

Indiana May Report.—Dr. W. T. Gott, Secretary of the Indiana Board of Medical Registration and Examination of Indiana, reports the written examination held at Indianapolis, May 22-24, 1906. The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 750 out of 1,000 possible points. The total number of candidates examined was 179, of whom 170 passed, including 7 osteopaths, and 9 failed, including 3 osteopaths. The following colleges were represented:

PASSED.

College.	Year. Grad.	Per Cent.
Indiana Med. Coll. (1906) 76.1, 76.1, 77.4, 77.4, 79.7, 80.5, 81, 81, 81.5, 82, 82.1, 82.1, 82.8, 83.6, 84.5, 85.1, 85.4, 85.8, 85.9 86, 86.2, 86.8, 86.9, 86.9, 87, 87.3, 87.4, 87.5, 87.6, 87.6, 87.7, 87.9, 87.9, 88, 88, 88.2, 88.2, 88.3, 88.5, 88.5, 88.6, 88.7, 88.7, 8.88, 88.9, 89, 89, 89.1, 89.1, 89.1, 89.2, 89.3, 89.4, 89 4, 89.5, 89.6, 89.8, 90, 90.1, 90.2, 90.2, 90.2, 90.4, 90.4, 90.5, 90.6, 90.6, 90.7, 90.7, 90.7, 90.7, 90.7, 91, 91.1, 91.1, 91.1, 91.2, 91.2, 91.2, 91.2, 91.3, 91.4, 91.5, 91.6, 91.6, 91.6, 91.9, 92, 92, 92.1, 92.1, 92.2, 92.4, 92.5, 92.5, 92.5, 92.6, 92.6, 92.6, 92.9, 93.2, 93.3, 93.4, 93.8, 93.9, 94.2.		
Medical College of Indiana	(1904)	91.2
Physio-Med. Coll. of Indiana (1904) 88.4; (1906) 84.7, 86.9, 88.2, 89.4, 93.3.		
Eclectic Med. Coll. of Indiana (1905) 79.7; (1906) 86.2, 87.4, 88.3, 89.8.		
Ft. Wayne Coll. of Medicine	(1905)	78.9
Hahnemann Med. Coll., Chicago	(1906)	88.5, 89.6
Bennett Eclectic Med. Coll., Chicago	(1905)	90.3 91.8
Chicago Homeo. Med. Coll.	(1904)	91.2
Illinois Med. Coll. (1905) 87.6, 89.3, 89.4, 89.5	(1906)	85.7 86.4
Rush Med. Coll.	(1902)	92.7
College of P. & S., Chicago (1894) 93;	(1905)	85.8
Northwestern Un'v. Med. School	(1904)	89 6
University of Louisville (1905) 83.4, 89.1,		89.5
Kentucky School of Med.	(1905)	84.6
Kentucky University	(1905)	85.6 88 3
Louisville Med. Coll.	(1903)	91.3
Southwestern Homeo. Med. Coll.	(1905)	83.9
Johns Hopkins Med. School	(1904)	89.8
Baltimore University	(1897)	82.9
University of Michigan	(1905)	89.2
College of P. & S., St. Louis	(1891)	89.5
St. Louis Univ. (Mar on Sims Beaumont Med. Coll.)	(1905)	81.7
New York University	(1891)	94.4
Toledo Med. Coll.	(1905)	86.
Eclectic Med. Inst. (1884) 84 9; (1903) 75.5; (1904) 83; (1905) 93.2. (1906) 82.8, 86, 86.6, 91.3.		
Jefferson Med. Coll.	(1905)	91.1
Med. Coll. of Ohio	(1902)	90.4
Ohio Med. University	(1906)	93.7
Wisconsin Coll. of P. & S.	(1906)	94.3
University of Toronto	(1905)	89.7
Edinburgh University, Scotland	(1901)	89.2

FAILED.

Indiana Med. Coll.	(1906)	63.3, 72.1, 72.2, 74.1
Med. Coll. of Indiana	(1904)	69.2
Southwestern Homeo. Med. Coll.	(1903)	73.3

The following questions were asked:

ETIOLOGY AND HYGIENE.

1. Give etiology and hygienic management of scarlatina. 2. Croupous pneumonia. 3. Pulmonary tuberculosis. 4. Typhoid fever. 5. Summer diarrheas of infancy and childhood.

LARYNGOLOGY AND RHINOLOGY.

1. Give diagnos's and treatment of nasal polypi. 2. What constitutional diseases may present local manifestations in the nose?

MEDICAL JURISPRUDENCE.

1. What organ is generally the first and which the last to undergo putrefaction? 2. How would you distinguish between an incised wound made before and after death?

NEUROLOGY.

1. Give etiology of multiple neuritis. 2. What are the diagnostic symptoms of cerebral tumor? 3. Give diagnostic symptoms o multiple sclerosis.

OPHTHALMOLOGY AND OTOLOGY.

1. Give symptoms, diagnosis, prognosis and treatment of gonorrheal conjunctivitis. 2. Give etiology and treatment of blepharitis. 3. Give tests for hearing, or how would you test hearing?

PEDIATRICS.

1. (a) When should the treatment of congenital talipes be commenced? (b) State best method for treatment. 2. Give etiology and treatment of cholera infantum.

MATERIA MEDICA AND THERAPEUTICS (ECLECTIC).

1. Give indications for an emetic and name remedies you would use to produces emesis. 2. Name two remedies classed as emmenagogues and give specific ind cations for each. 3. Give specific indications and dose for (a) bryonia, (b) ipecac, (c) veratrum, (d) quinin and (e) rhus tox. 4. What would you give a patient who presented symptoms as follows: Flushed face, unnaturally bright eyes and contracted pupils, with increased heat of the head? 5. What would you give a patient with symptoms as follows: Dusky redness of the surface, patient dull and inclined to sleep, eyes dull and pupils contracted? 6. Name two anthelmintics, giving dose of each. 7. Give indications for an alkali. 8. Give indications for an acid. 9. Write a prescription in which you use sodii sulphatis, and give indications for its use. 10. Name three antiseptics.

THEORY AND PRACTICE OF MEDICINE (ECLECTIC).

1. How would you distinguish the convulsions of tetanus from an overdose of strychnin? 2. Give symptoms, differential diagnosis and treatment of acute catarrhal gastritis. 3. Give etiology, symptoms, differential d agnosis and treatment of arterioscleros 4. Give symptoms, complications, diagnosis, prognosis and tre ment of Addison's disease. 5. Give symptoms, diagnosis and trea ment of uremia. 6. Give treatment of neurasthenia. 7. Ho would you differentiate acute softening of the brain from hemo rhage? 8. What is your idea of constipation and how would yo treat it? 9. Write a prescription for the hemorrhage that ofte occurs in typhoid fever. 10. Give differential diagnosis and treatment of diphtheria.

MATERIA MEDICA AND THERAPEUTICS (HOMEOPATHIC).

1. Give indications for the use of iodoform internally. 2. Give the physiologic action and therapeutic indication for hydrastis canadensis. 3. Mention indications for employing massage. 4. Give therapeutic individuality of kali iodatum. 5. Name two remedies frequently indicated in dropsical effusions. 6. What symptoms determine choice of sulphur in chronic diseases? 7. Differentiate the cough symptoms of ipecacuanha and sanguinaria. 8. Give therapeutic individuality of kali chloricum. 9. Give guiding symptoms of apis mellifica. 10. Name bowel symptoms of mercurous sol.

THEORY AND PRACTICE OF MEDICINE (HOMEOPATHIC).

1. Give diagnosis and etiology of osteomyelitis. 2. State varieties of neuritis and most common cause of each. 3. Name three remedies most frequently indicated in the treatment of chronic nephritis. 4. Give the forms of pneumonia, and differentiate from acute bronchitis. 5. Give etiology, prognosis and treatment of acute articular rheumatism. 6. Define hypnosis. Should it ever be employed in the treatment of disease? If so, when? 7. Give your idea of the merits of suggestive therapy. What class of diseases is most easily influenced by mental processes? 8. Define phlebotomy, and state when it should be employed. 9. Define (a) contagion, (b) infection, and give means for prevention of each. 10. Name two diseases affecting the glandular system, and give remedies ordinarily indicated in each.

MATERIA MEDICA (PHYSIOMEDICAL).

1. What are the therapeutic properties of caulophyllum? 2. What are the properties of cimicifuga race and what is the dose of the fl. ext.? 3. Name three remedial agents that are nervine relaxants. 4. Name agents that increase renal action. 5. Give the therapeutic properties of quinin. 6. In what condition and under what circumstances would you give hydrochlorate of quinin in preference to the sulphate? 7. Give conditions in pneumonia in which you would combine capsicum and lobelia, and when would you give lobelia alone, and why? 8. Mention five sanative agents that promote increased hepatic action. 9. In what particulars do the cactus grand, and the cerusbonplandii differ in influencing the heart's action, and why? 10. What is the dose and the therapeutic influence of fl. ext. pulsatilla?

THEORY AND PRACTICE (PHYSIOMEDICAL).

1. What are the most common causes of secondary anemia? 2. Give pathognomonic symptoms and treatment in the first stage of pneumonia. 3. A child, one year old, hitherto healthy, has sudden seizure of pain in the region of the stomach; gets cold extrem-

ities, followed by temperature of 101°. Similar attacks follow each day, fever gradually increasing after each attack, declining after each exacerbation, but not entirely disappearing Tongue broad, pale, with white fur Appetite variable digestion fair. Bowels irregular spleen slightly enlarged After six months there is very marked anemia Number of leucocytes unchanged number of red corpuscles much reduced Hemoglobin 40 Give diagnosis and treatment 4 Differentiate between typhoid and appendicitis 5 How would you manage a case of pulmonary tuberculosis in an ordinary family and home, with a view to the prevention of infection of others? 6 Give diagnostic symptoms of rubeola and scarlatina 7 What are the positive evidences of anemia and what is the treatment if due to malaria the plasmodia being present in the blood? 8 In a case with no evidence of organic lesions, the patient complains of pain referred to the stomach and esophagus with a feeling of constriction, symptoms relieved by food in the stomach, worse when stomach is empty bowels sore and painful, with diarrhea What would be your diagnosis and treatment and directions as to diet? 9 At what points are the lesions in each of the four cardinal types of aphasia and how is each type manifest? 10 Give differential diagnosis of apoplexy and epilepsy with mode of management of each.

GYNECOLOGY.

1. Define (a) sepsis, (b) asepsis; (c) give aseptic technic. 2 Give symptoms and diagnosis of laceration of the cervix 3. Give (a) indications for hysterectomy (b) technic of vaginal hysterectomy. 4 Give surgical treatment of cystitis 5 Give technic of curettage What is its therapeutic purpose? 6 Give differential diagnosis of benign adenoma (polypoid endometritis) and malignant adenoma (carcinoma).

CHEMISTRY.

1 Give difference between methyl and ethyl alcohol and give common name for each 2 What is muriatic acid and its formula? 3 What is specific gravity of healthy urine? 4 Give a reliable test for albumin, bile, blood and sugar in the urine 5, Give test for free acid in the stomach contents

ANATOMY.

1 Name and locate the colonic flexures 2 Describe the celiac axis 3 Give the boundaries of the normal liver 4 Give the names and origin of the nerves that supply the tongue 5 Describe the internal saphenous vein 6 Give the relations of the external carotid artery 7 Name the large blood vessels that comprise the portal system of veins 8 Make a drawing showing the origin and communications of the spinal accessory, pneumogastric and glossopharyngeal nerves 9 Describe the os calcis Give its relations 10 What bones of the tarsus are on the proximal side of the line of Chopart's amputation?

MATERIA MEDICA AND THERAPEUTICS (REGULAR).

1 Give the derivation of adrenalin and its physiologic action 2 Name a vasoconstrictor, give its effect on blood pressure and an indication for its therapeutic application 3 Name a vasodilator, give its effect on blood pressure and an indication for its therapeutic application 4 Give technic of hypodermoclysis and an indication for its use 5 What is the composition of normal salt solution? 6 What value do you attach to sunlight and fresh air as therapeutic agents? 7 Name an efficient urinary antiseptic. 8 How would you apply cold water as an antipyretic? 9 Name an antidote to arsenic 10 Name an antidote to carbolic acid

INTERNAL MEDICINE (REGULAR).

1 Give a predisposing cause, symptoms and treatment of cerebral hemorrhage 2 What is the significance of diminution or absence of the second sound of the heart during the progress of a croupous pneumonia? 3 Describe Cheyne Stokes' respiration and give its prognostic significance 4 On what findings would you base a diagnosis of acute Bright's disease? 5 Name some remote pathologic results of syphilis 6 Give symptoms and diagnosis of scarlatina and name some of the most frequent sequelæ of the disease 7 Give symptoms and treatment of intestinal hemorrhage of typhoid fever 8 Give common cause and treatment of diarrheas of infancy and childhood 9 How would you treat hemoptysis? 10 Give method of positive diagnosis and treatment of diphtheria

OBSTETRICS.

1 Does Nature ever fail to set in motion forces that commence labor at the termination of full term? If so, state causes and proper procedure 2 Name conditions warranting Cesarean section Give technic of operation 3 Is the production of abortion ever legally justifiable? If so state conditions of justification 4 What advice would you give the *enciente* as to her manner of living during the period of gestation, in order that labor may be made easier? 5 In case positive diagnosis of prenatal death has been established, would you attempt to bring about expulsion of uterine contents? If so, why and when? 6 What foods are most suitable for artificial feeding of the newly born? Give method of modifying or preparing food for best results in artificial feeding 7 State conditions under which the artificial feeding of infants should be undertaken 8 Is puerperal infection preventable? If so give methods of prevention 9 Give management of breech presentation 10 Differentiate the convulsions of eclampsia from hysteria

SURGERY.

1 Give differential diagnosis of appendicitis and small ovarian cyst 2 Name the differential clinical and pathologic points of carcinoma and sarcoma 3 Name the fractures of the skull 4. Give diagnosis and treatment for hemorrhoids 5 Give diagnosis and treatment of Potts' disease 6 What is the best known means for an end to-end anastomosis of the intestine? 7 Give treatment for fracture of middle third of the femur 8 What structures would be divided in an amputation through the middle of the arm? 9 Give diagnosis of gallstones and the technic for the operation 10 Give treatment for stricture of the urethra in the male

PATHOLOGY AND BACTERIOLOGY.

1 What pathologic conditions arise as secondary to mitral insufficiency? 2 What do you understand by the general term degeneration? Name the forms of degeneration 3 Write in columns the names of the various forms of disease produced by bacteria 4 What is the most common pathologic factor in inflammation? 5 Define in contrast sarcoma, fibroma and carcinoma 6 How may the tubercle bacillus be isolated? How may it be cultivated? 7 Mention five varieties of anaerobic bacteria 8 What conditions are necessary for sterilization by steam at low pressure and at high pressure? 9. How would you examine the blood for Fraenkel's pneumococcus? 10 How would you differentiate bacteriologically between tonsillitis and diphtheria?

PHYSICAL DIAGNOSIS

1. Give diagnosis of cardiac hypertrophy affecting (a) the left ventricle, (b) the right ventricle 2 Give physical signs of pericardial effusion 3 Give diagnosis of thoracic aneurism 4 Give respiration rate in (a) the newborn; (b) the adult. 5 How may the normal movements of the diaphragm be rendered visible (Litten's phenomenon)?

PHYSIOLOGY.

1 Explain the difference between the function of the kidney and that of a true glandular organ. 2 What organs of the body are purely excretory in their office? 3 What becomes of the gastric and pancreatic juices after they have performed their offices in the digestion of a meal? 4 What do you understand by common sensation and special sensation? 5 Give physiologic definition of the terms systole and diastole, and give the behavior of the blood current during each 6 Define and give the significance of the dicrotic pulse 7. Give the physiologic composition of the blood, with the functions of each ingredient.

Vermont July Report.—Dr W. Scott Nay, Secretary of the Vermont State Board of Medical Registration, reports the written examination held at Burlington, July 10 12, 1906. The number of subjects examined in was 12; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 33, all of whom passed. The following colleges were represented:

PASSED

College	Year. Grad	Per Cent
University of Louisville	(1905)	75.2
Boston University	(1906)	77.4
Albany Med Coll	(1905)	84
Dartmouth Med Coll	(1904)	79.2
University of Vermont	(1904) (1905) (1906)	77.1 79 75.1, 76.1, 76.1, 76.6, 76.7, 76.9, 77.1, 77.4, 77.6, 77.9, 78.1, 78.1, 78.1, 78.8, 79, 79.1, 79.1, 79.2, 79.2, 80.2, 80.7, 80.7, 81.2, 81.6, 81.7, 81.8, 84.3

The following questions were asked:

PRACTICE OF MEDICINE

1 Give the differential diagnosis between chronic bronchitis, tuberculosis of the lungs, pneumonia and pleurisy 2 Give the etiology, symptoms and proper treatment of measles 3 Describe urticaria What are its most common causes and what treatment would you recommend for it? 4 What are the symptoms and general course of aneurism of the aorta and how would you treat a case? 5 Describe the life history of *Tænia solium* the symptoms which it causes and its proper treatment 6 Describe the etiology and pathology of cirrhosis of the liver 7 Describe the pathology and symptoms of Addison's disease 8 How would you distinguish pyelitis from cystitis? Give treatment for each 9. Give causes, symptoms and proper treatment for malarial fever 10. Give etiology, symptoms and prophylaxis of yellow fever

SURGERY.

1 Name the principal bacteria and the surgical diseases produced by each 2 Name the varieties of wounds and seven methods of stopping hemorrhage 3 Name the usual methods of healing in wounds and describe how it is accomplished 4 Describe thrombosis and embolism, how caused symptoms and treatment 5 Give cause, symptoms and treatment of caries and necrosis 6 Give causes and treatment of ununited fracture. 7. Describe in detail the method of ligating arteries 8 Differentiate between coma from injury and apoplexy uremia, epilepsy, diabetes, opium poisoning and alcoholic intoxication 9 Diagnose a case of hip joint disease 10. Describe in detail removal of the breast.

LEGAL MEDICINE

1. Define syncope, asphyxia and coma Give examples 2 What is the difference between a medicine and a poison? 3 Explain the terms mania monomania, dementia and idiocy. 4 On what would you base your opinion that a child had been born alive at term? 5. Give causes of death during the birth of a child

THERAPEUTICS.

1 For what particular symptoms would you prescribe the following? Grindelia robusta, hyoscyamus hydrastis gelsemium, cactus, arom sulph ae, veratrum viride, croton oil 2 Write a prescription for each of the following conditions. Hematuria, cystitis, impetigo, herpes zoster, capillary bronchitis, acute rheumatism 3 What drugs would be indicated in the treatment of erysipelas? 4 How would you manage a case of belladonna poisoning? 5 Give the external and internal uses of (a) silver nitrate, (b) carbolic acid

CHEMISTRY

1. (a) What is meant by the term molecule? (b) What is believed in regard to movements of molecules in gases, liquids solids? 2 In case of defective drainage causing sickness, how would you detect such in water? State your tests 3 How would you test a suspected mixture for arsenic: State the test you would use and the reactions What other substances might be mistaken for arsenic and how can they be distinguished? 4 (a) What is the difference between a ferrous and a ferric salt? (b) Illustrate the difference between symbol, formula, equation What information does each convey? 5 (a) Name the organic and inorganic constituents of urine (b) Name the abnormal constituents of urine and give tests for same

OBSTETRICS

1 Give symptoms of pregnancy 2 Give treatment of abortion. 3 Describe a normal labor 4 Give mechanism of face presentation 5 How and for what reasons would you perform version? 6 What complications may result from infection after delivery?

7. What is *eclampsia*? 8. What is inertia and cause of same? 9. Describe application of forceps to a head presentation. 10 What is treatment of postpartum hemorrhage?

GYNECOLOGY.

1. Give symptoms indicative of pelvic disease. 2. Treatment of ovaritis. 3. Differentiate uterine fibroid and ovarian cyst. 4. Give treatment of vaginal catarrh. 5. What is amenorrhea and when does it occur?

PHYSIOLOGY.

1. Give the classifications of efferent nerves. 2. Give the properties and functions of the medulla oblongata. 3. State the physiologic properties of nerve cells. 4. Give the action of the salivary secretion on starch. 5. Give the products of intestinal digestion and state the disposition made of these products. 6. Describe the plasma of the blood and give its constituents. 7. Describe the changes of the blood during coagulation. 8. Name the most frequent abnormal constituents of urine and way of detection in three of them. 9. Describe the lymphatic system, giving its functions. 10. How is the temperature of the body kept at the standard?

HYGIENE.

1. Name the contagious diseases for which you would quarantine. 2. Give the rules and time for which you would quarantine four of them. 3. State the duties and obligations of the family physician in regard to the hygiene of school children. 4. Tell how you would build and furnish a school house, observing hygienic rules. 5. How would you manage a case of phthisis pulmonalis to avoid danger to other members of the family?

THEORY AND PATHOLOGY.

1. Name five self-limited diseases. 2. Why does not every person exposed *to an infectious disease take it? 3. Explain the more* recent theories of immunity. 4. What are phagocytes and what is their rôle in the prevention of disease? 5. What are the symptoms and what are the pathologic changes in progressive bulbar paralysis?

ANATOMY.

1. Name and describe four classes of tissue which enter into the formation of the human body. 2. Describe the bony pelvis and state what bounds the cavity of the pelvis above. 3. Give three general classifications of joints. Describe the elbow joint. 4. Name the muscles of the abdomen and give the origin, insertion, nerve supply and action of any one of them. 5. Name the cavities, openings and valves of the heart. 6. Give the collateral circulation when the brachial artery has been ligated just below its profunda branches. 7. Describe Scarpa's triangle and name its contents. 8. Name the organs and parts of organs located in the left hypochondriac region. 9. Give the columns, fissures and blood supply of the spinal cord. 10. What abdominal viscera and parts of viscera have no peritoneal investment?

BACTERIOLOGY.

1. What are the general requisites for a nutrient media? 2. Name and describe the most common pyogenic organism. 3. How would you prove a certain specific micro-organism to be the cause of a certain specific disease? 4. What is there peculiar in the behavior of the tubercle bacillus toward staining solutions? 5. What micro-organisms would you expect to find in the pus from a psoas abscess?

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Cystitis.

In the treatment of cystitis, Yeo in *Clin. Ther.* recommends the following combinations:

℞. Terebinthinæ (pure)
Ext. gentianæ, āā ....gr. xlv 3|

M. Ft. pil No. xxx. Sig.: One pill three times a day, followed by two tablespoonfuls of lime water in milk.

Or,

℞. Acidi benzoici ....gr. lxxv 5|
Syr. aurantii ....ʒv 20|
Aquæ dest., q. s. ad.................f. ℥x 300|

M. Ft. mistura. Sig.: One tablespoonful every two hours in water.

Or,

℞. Sodii bicarb. ....gr. lxxv 5|
Decoctio uvæ ursi ....℥vi 180|

M. Ft. mistura. Sig.: One tablespoonful every two hours.

If there is a marked catarrhal condition and the urine is of foul odor the following combination is advised:

℞. Resorcini ....gr. xlv-lxx 3-4|65
Aquæ dest. ....f. ℥iii 90|

M. Sig.: To be mixed with an equal quantity of warm water and used as a solution for washing out the bladder in chronic cystitis.

Or,

℞. Acidi borici ....℥ss 15|
Glycerini ....℥i 30|
Aquæ dest., q. s. ad.................f. ℥v 150|

M. Sig.: To be mixed with an equal quantity of warm water and used as an irrigation.

Or,

℞. Aluminis
Zinci sulph.
Acidi carbolici, āā.................℥ss 15|
Aquæ dest., q. s. ad ....f. ℥x 300|

M. Ft. lotio. Sig.: To be diluted ten times with sterilized water and about one pint of the mixture to be injected daily into the bladder.

Internally the following combinations are recommended:

℞. Buchu fol. ....ʒii 8|
Uvæ ursi fol.................ʒii 8|
Aquæ ferventis ....f. ℥vi 180|

Macerate for two hours, strain, and add:

Liquoris potassæ ....f. ʒi 4|
Tinct. cinnamomii,
Tinct. hyoscyami, āā.................f. ʒiii 12|

M. Ft. mistura. Sig.: Two tablespoonfuls three times a day.

In case of phosphatic deposits in the urine the following combination is recommended:

℞. Acidi hydrochlor. fort.................m. iii |20
Aquæ dest. ....f. ℥vi 180|

M. Sig.: To be used as a wash for the bladder.

Psoriasis.

According to Hyde, arsenic ranks first in the treatment of psoriasis and he further emphasizes that whatever failures are experienced with this preparation in the treatment of other diseases its value must not be ignored in this one. It is unsuited, however, for all cases of psoriasis occurring with acute symtoms, such as subjective sensations and unusually vivid redness of the patches. The preparation usually employed is Fowler's solution, beginning with small doses and gradually increasing the dose to the proper proportions, at the same time keeping the patient under constant observation during its administration.

The arsenate of sodium or the arsenate of iron are sometimes recommended.

In the gouty cases Hyde advises the following combination:

℞. Potassii acetatis ....℥i 30|
Spts. etheris nitrosi ....f.℥ss 15|
Vini colchici ....f. ʒii 8|
Syr. aurantii ....f. ℥iss 45|

M. Sig.: One dessertspoonful after meals in water.

Locally for the eruption, green soap in combination with tar and alcohol serves a good purpose combined as follows:

℞. Tinct. saponis viridis ....℥ii 60|
Olei picis ....f. ℥i 30|
Alcoholis ....f. ℥ii 60|

M. Sig.: Apply locally.

Or,

℞. Saponis viridis ....℥iv 120|
Olei rusci
Glycerini, āā.................f. ℥i 30|
Olei rosmarini ....ʒiss 6|
Spts. vini rectif. ....f. Oss 250|

M. Ft. linimentum. Sig.: Apply locally.

Or,

℞. Sulphuris sublim.
Olei rusci, āā.................℥ss 15|
Saponis viridis
Adipis, āā.................℥i 30|
Cretæ prep. ....gr. l 3|20

M. Ft. unguentum. Sig.: To be applied locally.

Or,

℞. Olei picis ....ʒi 4|
Vel
Olei rusci
Olei amygdali ....℥i 30|

M. Sig.: Apply locally.

The local treatment of the scalp or the face with some of the foregoing combinations can not be carried out because of their disagreeable odor, but as a substitute he recommends the following:

℞. Hydrarg. chloridi mitis ....gr. xxx 2|
Lanolini ....℥i 30|

M Ft unguentum. Sig: Apply locally.

Or,

℞.	Tinct benzoini	ʒss	2	
	Lanolini	℥i	30	

M. Ft unguentum Sig.· Apply locally

Pyelitis.

In cases of chronic pyelitis the following is recommended internally·

℞	Quininæ tannatis	gr. xv	1	
	Sacchari albi	gr. xxx	2	

M Ft cap No vi Sig: One capsule three times a day.

In calculous pyelitis due to lime or uric acid deposits the following may be used:

℞	Sodii phos	℥i	30	
	Sodii bicarb	℥ii	60	
	Lithii carb	ʒiiss	10	

M Ft pulvis Sig: One teaspoonful in a pint of water three times a day.

In the treatment of uric acid calculi Yeo states that excellent results have been obtained by the administration of large doses of glycerin by the mouth, the good effects being due to changes produced in the urine

The amount given is one to four ounces dissolved in an equal quantity of water taken between meals every two or three days for a period of several days Some authors state that it renders the specific gravity such as to produce a change in the position of the calculi in the pelvis of the kidney

Malaria.

In the administration of quinin hypodermically. quinin hydrochlorate is to be preferred, according to J. C. Wilson in his "Text Book of Applied Therapeutics," as follows:

℞	Quin hydrochlor.	gr. lxxv	5	
	Aquæ dest	f. ʒiiss	10	

M Sig· Fifteen drops at one injection

Or the following solution after Kobner's formula·

℞	Quin hydrochlor	gr viii xv		56 1
	Glycerini			
	Aquæ dest, āā	ʒss	2	

M Sig· To be injected at one time, luke warm.

By some authorities the following combination is recommended:

R	Antipyrini	gr vi		30
	Quin hydrochlor	gr xv	1	
	Aquæ dest	f ʒss	2	

M Sig· To be injected at one dose

Wilson recommends the chlorhydrosulphate as follows:

℞	Quin chlorhydrosulphatis	gr lxxv	5	
	Aquæ dest	f. ʒiiss	10	

M Sig: Fifteen drops at one injection.

Quinin sulphate may be given hypodermically when combined with tartaric acid, as follows:

R	Quin sulphatis	gr. xv.	1	
	Acidi tartarici	gr viii		50
	Aquæ dest	f. ʒiiss	10	

M Sig: To be given hypodermically

By the mouth the following combinations are recommended in the *Pract Med Series*·

R	Quin sulph vel hydrochlor			
	Salol, āā	gr. xl	2	65
	Phenacetini	gr. xxx	2	

M Ft cap No xii Sig: One capsule every three hours

Or

R	Quin sulphatis	gr. lxxx	5	
	Acidi hydrochlor. dil			
	Tinct zingiberis			
	Tinct opii camphor, āā	f. ʒii	8	
	Syr limonis	f. ℥ii	60	
	Aquæ, q s ad	f. ℥iii	90	

M Sig: One tablespoonful every four hours in water

To correct the anemia following an attack of malaria the following is advised:

R	Quin sulphatis	ʒiss	6	
	Ferri reducti	ʒi	4	
	Ext nucis vomicæ	gr. viii		50
	Acidi arsenosi	gr. i		06
	Ext colocynth. co	gr. x		65
	Podophyllini	gr. ii		12

M Ft cap No lx Sig: One pill after each meal.

Medicolegal

Aggravation of Effect of Injury By Use of Opiates.

The Supreme Court of North Dakota holds, in the case of Pyke vs. City of Jamestown, that the aggravation of the consequences of a personal injury by the use of opiates, taken under the direction of a reputable physician to alleviate the pain resulting from the injury, is not a defensive fact in an action to recover damages for the injury. The necessity for the use of opiates arises in such case from the negligent act causing the injury, and not from any negligence of the person injured And this, the court suggests, would be true even if the physician erred in his treatment.

Liability of Board of Health Members From Smallpox Hospital.

The Supreme Judicial Court of Massachusetts says, in Barry vs Smith and others, an action against the members of a city board of health for damages from a smallpox hospital located adjoining property of the plaintiff's, that if a rope was put around his driveway and that brought within the hospital grounds by the defendants, or by persons in their presence and under their direction, the defendants were liable. As members of the board of health *they had no right to take the plaintiff's* land without action under the statute. It is not true that a public officer is exempt from liability for all acts done in his official capacity. However, the court assumes that, if a case of smallpox had broken out in the plaintiff's house, his driveway could have been roped off in regulating the disease on his premises as a menace to the public. Moreover, in fixing on the location of the hospital the defendants were exercising a discretion which the Legislature had required them to exercise as public officers, and their decision on the question, being quasi judicial or quasi legislative, was final, and it was not competent to make them liable for a mistake or for negligence in the exercise of it, that is, in the location of the hospital. Where a plaintiff suffers a loss of rents from the location of a smallpox hospital in the neighborhood on land leased for the purpose, but where the hospital is not improperly conducted, he has no remedy. But if the defendants were personally negligent in the maintenance of the hospital, and in consequence of that negligence the hospital became a nuisance to the plaintiff's adjoining houses and land, the defendants were liable, provided their negligence was a misfeasance, as distinguished from a nonfeasance. If they were guilty of a nonfeasance only, no action would lie against them. It followed that the plaintiff did not make out a case against the board of health by showing that the hospital was a nuisance and that at the time it was under their control. The plaintiff must go one step further to charge the defendants with the nuisance, and prove that it was caused by acts of misfeasance on the part of the defendants, or by an act or acts done by another in the personal presence which would thus be the acts of the defendants

What Constitutes "Sunstroke."

The Supreme Court of Kansas says, in Continental Co vs. Johnson, that the latter party, by whom the action was brought, was a fluewelder, and while engaged in that occupation was overcome by heat from the forge or furnace near which he worked, and, in consequence thereof, became ill and suffered the loss of nearly a year's time. He alleged that his loss was due to sunstroke within the provision of an accident policy that loss of time due to sunstroke should be deemed to be due to external, violent, and purely accidental causes, and should entitle the insured to full benefits according to the terms of the policy. The company, on the other hand, insisted that the word "sunstroke" as used in the policy referred only to an effect produced by the heat rays of the sun

After reviewing the definitions and statements of a number of dictionaries and encyclopedias, medical dictionaries and works, the court says that it seems clear from them not merely that it is permissible to apply the word "sunstroke" to a condition produced by artificial heat, but that it accords with the best usage to do so; that such condition is comprehended within the ordinary meaning of the word wherever it is used with care and precision, whether in technical scientific treatises or in works designed for the general reader. Where the word is used carelessly or ignorantly it may well be supposed that reference is had to any temporary discomfort resulting from exposure to the direct action of the sun. So in Insurance Co. vs. Trefz, 104 U. S. 197, it was held that the statement of a witness that he had had an attack of sunstroke was not necessarily to be taken as an admission that his ailment was in fact a real case of sunstroke, properly so called. But in the drawing of an instrument of the character and importance of an insurance policy the presumption should be that language is selected to express with entire accuracy and correctness the agreements of the contracting parties. And in the present case the word "sunstroke" might be deemed to describe, or at least to be inclusive of, the condition properly called by that name, whether occasioned by solar or artificial heat, unless some special reason existed for giving it a different meaning.

There may be an apparent incongruity in calling that "sunstroke" which has no relation to any effect produced by the sun, but this is only to say that the word is not happily formed to suggest the idea it is employed to express. Etymology is not always a safe guide to the meaning of a term. It is no more imperative that "sunstroke" shall always mean a disorder caused by the sun than that "lunacy shall denote only an aberration due to the influence of the moon. The history of the word "sunstroke" seems to be that it was coined to describe any suddenly perceived ill-effects of sun heat; as observation disclosed that a definite morbid condition ordinarily accompanied or followed such an incident the word was applied to that condition in the belief that it was peculiar to cases having that origin; as advancing medical science revealed that such condition was a distinct disease and might and often did result from artificial as well as from solar heat, the physicians, instead of at once inventing a new and more appropriate name, broadened the application of the old one and their example was naturally and properly followed by others until the usage became general. Later, as a visible mark of the advanced learning on the subject, a more suitable term was originated to describe the disorder—"heat stroke," the growing employment of which may in time restore "sunstroke" to its primitive meaning.

It was argued, not without plausibility, that the language of the policy pointed to a conception of sunstroke as something of sudden and unexpected occurrence, more or less in the nature of an accident, and that this conception was only appropriate to an attack brought on by exposure to the sun's rays. But prostration resulting from heat emanating from a furnace may be as swift in its development and as startling in its effects as though it was occasioned by hot and humid weather. In each case there would be present some of the features of an accidental injury but neither would justify a recovery on an ordinary accident policy. In the only reported cases bearing on the subject (Dozier vs. Fidelity & Casualty Co. [U. S. Circuit Court], 46 Fed. Rep. 446, and Sinclair vs. Maritime Pass. Assur. Co. [English], 3 El. & El. 478), in disposing of the contention that the holder of an ordinary policy insuring him against accidental injuries is entitled to recover for disability due to sunstroke, it is held that sunstroke is not an accident but a disease. These cases are frequently referred to by the medical and legal writers and seem to be regarded as definitely settling the proposition to which they are directed. The discussion in the case first named tends to support the view that sunstroke may be caused by artificial heat, and the decision is cited as having that effect in Peterson & Haines' Text-Book of Legal Medicine and Toxicology, p. 491.

Wherefore, the court holds that the word "sunstroke," when used in an insurance policy in describing one of the risks covered, should not be interpreted as applying only to an effect produced by the heat of the sun, unless the context or other special considerations require it. The term explained denotes a condition produced by any heat. solar or artificial. Nor does the court think that the fact that in this case there was overexertion affected the liability of the company.

6 *New Management of Occipito-posterior Positions of the Fetal Head. M. C. O'Brien, New York.

1. Ears and Upper Air Tract in Sane.—Bryant shows the relation between insanity and functional derangement of the ear and upper air tract. Only three individuals out of 161 examined had perfectly normal hearing. Although the number of cases is not large enough to prove any point conclusively, they suggest that nasopharyngeal or aural diseases are far more prevalent among the insane than among normal individuals; and that sometimes hallucinations of hearing appear to be excited by subjective sensations of hearing; and that aprosectic psychosis is sometimes aggravated, i not excited by intranasal pressure. The prognosis for psychica improvement from treatment of the nasopharynx when nasa complications are a disturbing factor; and of the ear, whe active aural disease is a disturbing factor, is good. The prognosis is bad when there are chronic inactive aural conditions

2. Artificial Localized Hyperemia in Treatment of Ambulatory or Dispensary Cases.—Beer treated 90 odd cases in this way, including the following conditions and diseases: Prevention of infection, infected wounds and cellulitis of fingers or hand, abscesses, furuncles, carbuncles, acute suppurative adenitis, acute bursitis, contusions and more chronic conditions. Many of the cases in which constriction hyperemia was used were chronic.

6. Management of Occipito-Posterior Positions of Fetal Head.—O'Brien introduces either hand under the occiput, with or without anesthesia, grasps it firmly, having separated the middle and ring fingers to steady the neck, and makes counterpressure on the fundus, thus bringing the fetal body and head into one solid mass. With assistance he slowly rotates the mother to the genupectoral posture. This manipulation brings the occiput to the anterior position without traumatism to mother or child. Labor proceeds as when the patient is placed in the genupectoral position for prolapsed cord, or in the lateral obstetrical posture of the English school. O'Brien calls attention to the awkward movement which occurs when the patient's knee passes over the accoucheur, for the crux of the manipulation is to keep the head fixed steadily with the body curled on it.

14 *Improved Method of Ring Tests in Uranalysis. V. C. Pedersen, New York.

7. Stereoskiagraphy.—Stover describes stereoskiagraphy as consisting in making a pair of skiagrams of the part under examination, in such a way that by means of a special stereoscope the observer obtains from this pair of stereograms a view conveying perfect perspective. He considers the stereoskiagram to be a most useful means of Roentgen diagnosis.

10. Sternomastoid Breathing.—Chase presents a study of the dying state. Sternomastoid breathing consists of an up-and-down rocking movement of the head due to the breathing. He claims that sternomastoid breathing is a reliable sign of approaching death, and one which may serve the purpose of the physician in forming an estimate of the length of time the patient may live, without depending on signs of less value; its onset indicates that death is probably very close at hand, generally within half an hour; it is a definite symptom on which the physician may predicate his instructions or advice; it is a sign to mark the time when the *family* may be summoned to the bedside, or one which may regulate the other details of the death chamber.

11. **Spanemic Heart.**—Jackson defines the spanemic heart as one which, by reason of deficient nutrition of muscle, is dilated or dilatable. He believes it to be of three varieties: First, the heart, which is insufficiently nourished on account of general anemia. Second, the heart insufficiently nourished indirectly because of more or less persistent vasomotor failure, the blood being normal. Third, the insufficiently nourished heart from a combination of blood disease and vasomotor instability. He cites four cases in point.

12. **Strychnin in Pulmonary Tuberculosis.**—Milroy is of the opinion that strychnin should be used in pulmonary tuberculosis whenever the fresh-air treatment is not available, and that it may be used to advantage in conjunction with the *fresh-air* treatment.

14. **Improved Method of Ring Tests in Uranalysis.**—Pedersen's method is an improvement on the Boston method. The only required implement is a medicine tube about six inches long, three-eighths of an inch in diameter, tapered gradually to a rather small opening, and provided with a rubber bulb at the head, which it is well to secure at the neck of the tube with a rubber band or a tape, firmly in place to insure air-tightness. The technic is very simple, and comprises the following steps: While the air is forced and kept back from the tube by compressing the bulb the tip of the tube is immersed in the urine, which is sucked into the tube to its full capacity by allowing the bulb to expand. About half the capacity of the tube is now evacuated by again squeezing the bulb, which is maintained in a semiflat state after the drop of urine on the surface of the tube is wiped off against the neck of the urine bottle, the tip of the tube is dipped into the nitric acid. The bulb is then allowed to expand, thus sucking the acid into the tube, replacing the amount of urine evacuated by the foregoing step and thereby giving the two layers of fluid in the tube ready for the reaction—the upper, urine and the lower, acid. The tube is now stood aside in any convenient receptacle. At the juncture of the fluids the ring forms, which may be negative, doubtful, faint or positive. When the reaction is negative or positive no other step is necessary. When the ring is doubtful or faint the following detail proves the condition instantly: The tube is held over the acid bottle and the bulb slowly and uniformly compressed so that the faint ring or the supposed ring is made to descend unbroken into the taper of the tube. As the ring thus descends it does not change its thickness if the doubtful reaction is really negative, but if only faint, though really positive, the thickness of the ring at once is reduplicated and the observation of the reaction made certain.

17 Advantages of Separate Organizations for Training Schools and Hospitals. A. Worcester, Waltham, Mass.
18 Case of Primary Erysipelas of Pharynx. H. G. Langworthy, Dubuque, Iowa.

16. **Gastric Ulcer and Cancer.**—Graham distinguishes about four stages in gastric ulcer development and would expect cancer when it did develop to appear in the third or fourth stage or often to be the fourth stage. In the first stage of ulcer there is unusually good appetite with nutrition at par or even excessive; pain occurs from two to five hours after meals, when the stomach is empty or emptying itself. The second stage may be established some months later, following several intermissions with recurrences, each increasing more or less in severity; appetite is good, though perhaps not above normal; less satisfaction follows the hearty meal; pain is severe and comes sooner after food; distress or discomfort may be present even when so-called pain is absent. In the third stage, desire for food may remain, it may be fair or decreasing, but the patient is afraid to eat because of distress, pain, gas, vomiting, sour eructations, bloating or sour, burning stomach; there is but short food relief, if any; perhaps there are obstructive symptoms; loss of flesh is usual, and even cachexia may be present. Graham says that in the undoubted fourth stage (cancerous) the whole picture intensifies, "and he who runs may read." In Graham's series of cases the males and females ran in proportion of 4 to 1 and ranged in age from 29 to 75 years, the average being a little over 50. About three-fourths of the whole number presented themselves for amelioration of symptoms that had been pressing for one year or less. Twenty-three of the number who presented long histories complained of malignant symptoms only a year or less, the average in this number being a trifle more than five months. Pain was rather constant. In 8 the histories did not state either way, one patient said no pain, the remainder (73) openly declared for pain, most of them complaining rather bitterly. Vomiting was not recorded in 11 histories, 3 patients stated no vomiting, while the great number (68) complained more or less severely. In 42 the lesion was situated at the pylorus or lesser curvature, *in 3 at the cardia.* The location was not recorded in many of the inoperable cases, but the symptoms, for which the operation was undertaken, most often spoke for pyloric end or lesser curvature location.

Of the whole number operated on 67 patients had test meals and other routine stomach examinations, chemical and physical. Tumor was present 27 times and doubtful in 3 more. Dilation was present 54 and obstruction 36 times. In 32, free hydrochloric acid was present ranging from 1 to 50 acidity; combined in 32; lactic, 42; fatty, 19; both hydrochloric and lactic acids were found 13 times. Blood was found often. There were 39 cases in which a portion of the stomach was removed and examined. In 21 cases, 54 per cent., the pathologic evidence was good that cancer had developed on an old ulcer base; in 10 cases, 25.60 per cent., the evidence was fair that the same was true, while 8 gave no evidence of preceding ulcer irritation. Then in over three-fourths of the cases, 79.5 per cent., the pathologic evidence was good or fair that ulcer was first as a cause. Twenty-one of the 39 had long histories, 14 of which have good pathologic evidence, 6 patients whose histories were long, gave evidence considered only fair, 7 patients whose histories ranged from two months to two years gave good pathologic evidence, and 4, whose histories covered from one and one-half months to two years, offered fair proof. Histories and pathologic findings ran together both positive in over half the cases, 54 per cent.

21. **Vascular Tension in Chronic Illness.**—Hare emphasizes the importance of studying the vascular state and the degree *of the* blood pressure in respect to the diagnosis, prognosis and treatment in several states of disease because many medical men are still impressed with the idea that a tired heart should be stimulated to greater effort when in reality it should be given as much rest as possible by diminishing its burden

He says that it is quite remarkable how competent the heart is to attend to its functions if the physician is able to overcome vascular relaxation. In his experience there are only three drugs that are useful for this purpose, atropin, adrenalin and digitalis. If the physician will direct his treatment to the vessels, the heart will often be able to care for itself. The heart should be stimulated to increased effort when the real object is to decrease its burden and to diminish the toxemia which is destroying its function. If the high tension is due chiefly to spasm, nitroglycerin will do good but it will fail to a great extent if the condition is due to fibrosis. The combined effect of rest, massage and iodids, even when fibrosis is well developed, not only will often produce excellent results in that the state of a tired heart has been proved, but also results in a marked diminution of arterial tension, partly by a cardiac and partly by a vascular influence.

22 and 24. See abstracts in The Journal, June 23, 1906, page 1964.

26. **New Intestinal Parasite of Man.**—The organism described by Craig was observed in the feces of 6 natives who were patients in the hospital at the time. In 5 of the cases, the only symptom of importance was diarrhea, the stools being of watery consistency, and containing in three instances a small amount of blood and mucus. In none of these cases was *Entamœba dysenteriæ* present. The 6 patients were suffering from a very severe attack of acute amebic dysentery, and the new ameba was found in small numbers in conjunction with immense numbers of *Entamœbæ dysenteriæ*. In 1 case *Trichomonas intestinalis* was present. Craig has only observed the organism in natives of the Philippine Islands, although he has looked very carefully for it in Americans, some of whom lived in the tropics for some time. The parasite described passes through an amebic and a flagellate stage of development. Craig suggests for it the name *Paramœba eilhardia*.

29. **Peptic Ulcer of the Esophagus.**—Tileston reports three cases, all of them terminating fatally. In the first case, that of a woman, aged 58, the ulcer was situated 3 cm. above the cardiac opening of the stomach. The ulcer did not manifest itself until it perforated. In the second case, a man, aged 59, the lower end of the esophagus for a distance of 11 cm. was denuded of mucous membrane, except for a few small islands. The ulceration was very shallow, not involving the muscularity. In the third case, a woman, aged 37, there were several ulcers in the esophagus, and also a chronic ulcer of the stomach which perforated, causing the fatal peritonitis.

30. **Primary Sarcoma of Adrenal Gland.**—Blackburn reports another case of primary sarcoma of the adrenal gland which did not produce any symptoms of Addison's disease. The existence of the tumor was not suspected until after the death of the patient. The symptoms present suggested carcinoma of the stomach though the more characteristic symptoms were absent. Both adrenal glands were sarcomatous.

31. **Narcolepsy.**—In the case reported by Blodgett the causative action of a specific infected agent is believed to have been the source of the disorder. The grandfather of the patient was supposed to have had syphilis. Each member of the next generation bore some inherited constitutional taint, but in each individual the particular form of stigma varied from that of another. The patient who forms the subject of Blodgett's communication is of the third generation, a woman, 65 years of age. She began to notice her infirmity at about 22 years when the attacks appeared in the form of an irresistible inclination to fall asleep at all times of the day without cause or apparent provocation by surrounding circumstances; otherwise she seemed to be in her usual health. She falls into a perfectly natural slumber, wakens readily, and is apparently unaware that she has fallen asleep. There is no history of acute rheumatism or endocarditis, nor of any other infective or constitutional disease. The thyroid is neither hypertrophied nor absent.

32. **Unusual Antitoxin Rash.**—The patient, whose case is reported by Wilbur, gave a history of occasional urticaria following the ingestion of strawberries or shell-fish following the administration of a prophylactic injection of 1,000 units of diphtheria antitoxin; she complained of a feeling of fullness of the head. The face was flushed; there came total hyperemia of the skin with itching and the development of immense white weals. The lips, tongue and eyelids began to swell; there was dyspnea; the pulse at first rapid, became imperceptible at the wrist, although the apex beat was vigorous. These symptoms gradually became worse, but eventually, under stimulating treatment, they subsided.

34. **Causes of Sterility.**—Ward concludes that as conception is dependent on the four essential factors of healthy spermatozoa, normal ova, the union of the same, and the proper implantation of the fertilized egg, sterility is most frequently dependent on acquired pathologic lesions, and congenital defects, which defects and lesions produce sterility by interfering with one or more of the above-mentioned essentials. A large number of cases of acquired sterility are due to pathologic lesions producing such destructive changes in the tubes and ovaries as mechanically to prevent the union of the spermatozoa with the ova. Gonorrhea is the most frequent cause of such destructive lesions. Acquired sterility in a large number of instances, is due to chronic endometritis, which produces such pathologic changes in the endometrium as to prevent the proper implantation of the impregnated ovum. The cases of sterility associated with flexions, displacements, subinvolution, fibroids and other neoplasms, are due not to these conditions per se, but to the associated chronic endometritis which prevents proper implantation. A fruitful case of an unhealthy endometrium and of tubal disease, which either singly or together tend to prevent union of the male and female elements and proper implantation, is the chronic inflammation and congestion of the uterus and adnexa incident to subinvolution or sepsis which so frequently follows abortion, especially if treated by the expectant plan. We must be impressed by the great importance of gonorrhea in its relation to sterility, when we appreciate the fact that it not only renders the woman sterile, but is responsible nearly always for sterility in the male, gonorrhea thus being an etiologic factor in about 70 per cent. of the cases. As in nearly all instances of sterility in the woman due to gonorrhea, the infection has been innocently acquired by the wife, from her husband, the fault lies with the man in more than two-thirds of all cases.

37. **Meningocele of Unusual Size.**—In the case cited by Boyd the tumor occupied the occipital region, just below the posterior fontanelle; it measured 6 inches in its long diameter, and about 5 inches in the transverse diameter. The diameter of the opening in the occipital bone measured about 1 inch. The radical cure by amputation of the sac was performed without anesthesia. An incision through the skin at the neck of the tumor was made, and the sac exposed. The intracranial fluid was then slowly withdrawn. The infant showed marked evidences of shock, became pale, and for a time ceased to breathe. These symptoms, however, soon disappeared. The hernial sac was then dissected away, and closed in with a continuous suture of catgut. The skin was sutured with the same material. The infant made a rapid recovery from the operation. It gained in weight, and seemed to be well for three months, when it began to develop acute hydrocephalus. As the head increased in size, the body lost in weight.

The infant is now six months old, is poorly nourished, and has the characteristic separation of the sutures and the large bulging fontanelles.

40. **Symphyseotomy.**—In certain cases in which Cesarean section is contraindicated or for certain reasons might not be considered safe, Allen believes that symphyseotomy might be the means of saving the life of the child. Such an example would occur in the case of a pelvis contracted at the outlet (funnel-shaped pelvis), where the head had been forced into and fixed tightly in the brim, but could not be forced through. In such a case Cesarean section would be contraindicated, as a dead child would usually be the result, whereas symphyseotomy would usually give a good result to both mother and child. Also in the case of an impacted mentoposterior variety of face presentation, where flexion of the head or podalic version was impossible, symphyseotomy might be performed. In case of limited assistants and facilities and unfavorable surroundings, symphyseotomy will undoubtedly give better results than Cesarean section. If it has been definitely decided that a living child can not be delivered *per vias naturales*, Cesarean section should be the operation of election, believing that in the long run the best results to both mother and child can be obtained from that operation.

41. **Successful Cesarean Sections.**—Boyd reports two cases and reviews 12 cases reported previously. The indications for operation were the following: Flat, rachitic pelvis, with uterine myomata; scolio-rachitic pelvis; coxalgic pelvis; general contracted pelvis; obliquely contracted pelvis; rachitic pelvis; general contracted pelvis with exostosis over promontory sacrum; labor obstructed by anterior fixation of the uterus.

43. **Typhoid Fever Complicating Pregnancy.**—Foulkrod reports four cases of pregnancy complicated by typhoid and 1 case of pregnancy occurring during convalescence from a severe attack of typhoid fever. Foulkrod asks whether there is something generative by the pregnant woman which in a certain measure protects her from the more virulent attack of the toxins of typhoid fever, and that the course of the typhoid during pregnancy is undoubtedly modifying should it occur at such a time when the serum or cells have been charged with immunizing bodies.

46. **Temporal Fascia to Cover Cranial Defects.**—Beck refers to another possible method of covering over defects of the cranium which meets indications not met by other methods in use. He makes use of the strong fibrous sheaf of the temporal fascia inasmuch as this shows no marked tendency toward the formation of adhesions. In the case reported, the defect in the skull was about 3 inches long and 1 inch wide at its greatest diameter. There was a total absence of bone substance. This was 9 months after the original injury. Operation was undertaken mainly for the relief of pressure symptoms caused by extensive scar formation. An incision was carried around the temporal muscle down to the bone. Then this flap and its periosteum was loosened, care being taken not to tear the connecting link of periosteum which was kept as close to the bone suture as possible. Beck then folded over the entire flap at the lower edge of the defect and covered the gap with it. At the opposite end he chiseled off enough bone to enable him to make use of a small amount of dura to which he attached the aponeurotic end with thin catgut sutures. This aponeurosis was in direct contact with the brain, while the periosteum was on top. The skin surfaces were united. Up to the present time, six months after the operation, everything has gone well.

48. **Total Laryngectomy for Cancer.**—Bogart reports the case of a man, aged 46, who had an extensive carcinoma of the right vocal cord. The larynx was totally removed, four months ago, adopting the method advocated by Keen. The patient made a complete operative recovery.

49. **Treatment of Suppurative Peritonitis Following Appendicitis.**—That the peritoneal drain can be eliminated as a factor of importance in the treatment of diffuse suppurative peritonitis Hotchkiss believes has been shown by the outcome in 28 patients operated on since 1903. The McBurney muscle splint with or without the Weir extension to the posterior sheet of the rectus has generally been found sufficient for the necessary manipulations. As little ether as possible was administered, and every effort was made to complete all peritoneal work with as much speed and as little traumatism as possible. The appendix was systematically searched for and removed with as little disturbance to the intestines as need be. After its removal and the cleansing of the appendiceal site, the pelvis and lower abdomen were rapidly washed out with the Blake tube or the jacketted glass return-flow canula. In many cases the peritoneum was closed without attempting to remove the saline solution which had not run out. Drainage of the external wound down to the peritoneum was generally employed, from the fact that the wound was usually infected and needed it. Gastric lavage was given before the patient left the table, and, as a rule, an ounce or two of saturated solution of Epsom salts was introduced through the tube and left in the stomach. Morphin, as far as possible, was not given and the rectal tube with saline irrigation of the lower bowel was used generally at intervals of from six to eight hours for the first two days. If vomiting occurred the stomach was washed. The use of saline irrigations to the peritoneum through the small lateral incision, does not consume much time, and seems by diluting the remaining fluids to hasten their absorption, besides acting generally as any intravenous infusion would to hasten the removal of toxins by dilution besides stimulating the heart and circulation. Moreover, the actual ability of the peritoneum to cope with the inflammation seems to be increased and not hindered. In those cases in which the inflamed appendix is the cause of the peritonitis, the problem resolves itself into the rapid removal of the offending organ without evisceration, in all cases. The peritoneum has proven itself abundantly able to take care of the resulting inflammation, and drainage in the absence of local necrosis is often ill-advised and not based on sound physiology or mechanics. Gauze packing is not only unnecessary but frequently harmful, being probably responsible for increased mortality, not to speak of the incident damage to the endothelium, with the resulting adhesions.

50 and 52. See abstracts in The Journal, July 14, 1906, pages 146 and 147.

53. **Volvulus of Typhoid Intestine Simulating Perforation.**—In the case reported by Roberts the general symptoms of perforation were not present, but the pain, tenderness and rigidity seem to indicate some intra-abdominal lesion. On opening the abdomen neither serum nor pus were found. There was great difficulty in drawing up the cecal portion of the ileum, which seemed to be imprisoned in the pelvis and was collapsed. The ileum above this portion was moderately distended and freely movable. The appendix was short and bound firmly to the cecum by a web-like attachment. It was not swollen or

inflamed, and no concretion could be felt within it. Examination of about 2 feet of the ileum did not reveal any perforation or discoloration of the serosa to indicate the presence of internal ulceration. The pain and rigidity of the abdomen disappeared after the operation and the patient went through the remainder of the typhoid without abdominal symptoms other than such occasional pain that might be seen in ordinary cases. Consideration of this case seems to show that there was either a volvulus causing constriction of the lower portion of the ileum, or a mild appendicitis due probably to a typhoid inflammation of the mucous membrane. Because of the critical condition of the patient from typhoid fever, the absence of definite symptoms of appendicitis and the possibility of the condition of the appendix being congenital, the appendix was not removed. Roberts concludes that the symptoms were due to a sudden twist of the ileum, which was finally disentangled, when he turned the coils over and over in his endeavor to bring the cecal end of the small intestine up from the pelvis, in which it was imprisoned.

54. See abstract in THE JOURNAL, June 30, 1906, page 2016.

58. **Congenital Protrusion of Heart, Stomach and Spleen.**—Wintsch reports the case of full-term living celosomus. He has not found a similar case reported. There was complete protrusion of the heart, stomach and spleen. Labor seemed perfectly normal. The child weighed 7 pounds. It defecated and urinated normally. It became very cyanotic at times and the cyanosis was aggravated when pressing on the heart with the hand. The baby lived 2 days and 3 hours. It was fed by mouth with water and milk from the breast of the mother, which it retained. Just before death the child vomited a greenish fluid and bled from the mouth.

2. Position of Prostatic Surgery.—Extended experience has confirmed Nicoll's opinion that the first step in prostatectomy should be the opening of the bladder by the suprapubic route. This permits the completion of the diagnosis and the complete bi-manual examination of the prostate, and also a decision whether the urethra and mucous floor of the bladder are to be preserved intact or not. By whichever method of operating, vesicle or submucous, the surgeon, once the prostatic capsule has been opened, requires no other instrument than his finger, provided he is prepared to bring away, in whole or in part, the mucous urethra. Nicoll claims that in operating by the submucous method it is possible in 70 per cent. of the cases to enucleate the prostate by the finger alone without damage to the urethra or vesicle wall. He has never seen fatal hemorrhage following prostatectomy by any method. He claims that prostatectomy by enucleation constitutes the cure for senile hypertrophy of the organ and its effects. The cases in which he has performed enucleation are according to three series: The first series comprise 48 cases, with 4 deaths, a little over 8 per cent. The second series comprise 25 cases, with 5 deaths, or 20 per cent. Two of the 5 deaths occurred in cases in which Nicoll had previously, on account of the patient's feeble and unsound condition, discouraged the idea of operation. The third series showed 38 cases, with 2 deaths, or about 5.5 per cent.

3. Calculi in Prostatic Urethra.—Morton reports three cases in all of which the presence of the stone was associated with a stricture of the urethra. In none of the cases, however, was the stricture in front of the prostatectomy urethra. In one case it was scrotal, in another at the junction of scrotum and penis, and in the third near the meatus. Neither were the strictures very tight. In the first case 7 stones were removed, the largest weighing 208 grains. Only 1 stone was found in the second case, and a number of fragments, weighing 95 grains, in the third case.

4. Mechanism of Vesical Sphincter.—Green injected the bladder of certain men and youths with a suspension of bismuth, and then radiographed the pelvis. In every case he found that whether the bladder was fully distended or not, the outline of the organ was oval and not pear-shaped, and the urethra was sharply cut off from the bladder without a suggestion of a bladder neck. He concludes, as a result of his experiment, that there are reasons for believing that the sphincter of the bladder (the internal prostatic sphincter) plays a far more important part than Finger and Guyon credit it with, and that under ordinary circumstances it is by this muscle that the bladder is closed whether distended or not. There is evidence, he thinks, that when the internal sphincter does yield, it does so, not because it is overcome by the mechanical pressure of the urine in the bladder, but because its muscular fibers relax as a vital act in response to a nerve impulse preliminary to the evacuation of the urine. The normal act of micturition would appear to be as follows: As the bladder becomes distended with urine the vesical nerves are stimulated and evoke stronger and stronger contractions of the detrusor muscles, giving rise to the desire for micturition. To withstand the increased pressure of the urine the tone of the internal unstriped muscular sphincter is increased, and, if necessary, even the accessory voluntary urethral muscles are called into play. When a favorable opportunity for micturition occurs the internal sphincter is voluntarily relaxed, together with the rest of the unstriped muscular tissue of the posterior urethra, and the urine is expelled by the contraction of the detrusors.

14 *Unusual Forms of Anemia in Childhood. T. R. C. Whipham and A. N. Leathem.
15 *Plastic Surgery of the Renal Pelvis. J. W. T. Walker.

13. Rupture of Spleen.—In addition to reporting one case of rupture of the spleen, Simpson discusses 70 cases recorded in the literature since 1891. He advises immediate operation in all cases as soon as the diagnosis is made, even though there may not be much hope of saving the patient's life. In the 70 cases referred to, 42 patients were operated on; of these, 27 lived and 15 died, a mortality of 36 per cent. All those not operated on died. The causes of failure after operation were peritonitis, rupture of other viscera, especially the left kidney; injuries of the left pleura, other injuries, such as fracture of the base of the skull, and operation performed too late. The majority of patients show no abnormal effect except a transient anemia and leucocytosis, which swings back to normal in about a month, and an enlargement of the lymph glands, most often the left axillary and inguinal.

14. Unusual Forms of Anemia in Childhood.—Whipham and Leathem report three cases. The first 2 support their views as to the existence of that acute lymphemia without marked leucocytosis. The third case is an anomalous one and no diagnosis was made. The patient presented many points suggestive of pernicious anemia, but it was impossible to confirm this diagnosis.

15. Plastic Surgery of Renal Pelvis.—Walker reports the case of a young woman who had a movable tumor on the left side of the abdomen. It had existed about 7 months and followed the sudden attack of pain in that region, the result of carrying a heavy box downstairs. Four similar attacks of pain occurred later, some the result of exertion, others not. There were no urinary symptoms. The mass seemed to swing around a pedicle fixed above the umbilicus. Examination proved absolutely negative as to determining the nature of the tumor. A diagnosis of movable kidney without hydronephrosis was made. On cutting down on the kidney it was found to be attached to a large bladder-like cyst which was recognized as an enormously distended pelvis. The ureter below the mass showed no signs of dilatation. Walker excised a large triangular portion of the kidney pelvis in order to reduce its capacity and fix the kidney by a combination of decortication with non-decortication. The operation employed is described in full.

20 *Surgical Aspects of Colitis. P. L. Mummery.
21 *Syncytioma Malignum. J. T. Hewetson.
22 Two Cases of Branchial Fistula. W. Downie.

17. Silver Filigree in Hernia.—McGavin has employed the method described by Bartlett in 7 cases. One of these was a postoperative ventral hernia, 1 a case of extensive separation of the recti muscles and enteroptosis, 1 an umbilical hernia, and 4 were inguinal hernia. The outcome in all the cases was a successful one. McGavin calls attention to certain points which he believes are essential, such as the size of the filigree and its situation; the most suitable spacing of the loops, the removal of a filigree, and the filigree as a time saver.

18. Intestinal Obstruction in Children.—Edmunds reports a case of intestinal obstruction in a female child, aged 3 years and 4 months. The abdomen was opened through the right rectus muscle. On turning up the omentum a tag was found adherent to the tip of a short lateral protest of the small intestine. On one side of this the bowel was slightly distended and an obstruction could be demonstrated at the base of the process. The projecting portion of bowel was excised and showed that there was an acute kink of the intestine combined with great narrowing of the wound, forming a valve which presented a formidable obstacle to the passage of intestinal contents. The cut ends of the bowel were sutured together and the patient made a complete recovery.

20. Surgical Aspects of Colitis.—Mummery concludes that colitis should be looked on as a symptom rather than as a disease. A careful examination should be made. if possible, with the sigmoidoscope, and the cause of the colitis should be carefully determined before any treatment is adopted. If the colitis is due to disease in some neighboring organ, such as the appendix, kidney, or gall bladder, this condition should be treated by operation. If the colitis is secondary to malignant disease in the bowel, operation at the earliest possible moment affords the only chance of cure, and an early diagnosis is here of the utmost importance. If it is due to some local lesion, such as tuberculosis or actinomycosis, it must be treated locally; if necessary, by operative means, such as colotomy or enteroanastomosis. True mucous colitis is best treated by von Noorden's method of dietary, combined, if necessary, with irrigation of the colon. In some very obstinate cases, and especially in cases of ulcerative colitis, a temporary cecotomy, or colotomy, or enteroanastomosis seems to be the only method of cure, but should not be adopted until a careful trial has been made of palliative treatment.

21. **Syncytioma Malignum.**—As the result of an instructive case which occurred in his practice, Hewetson concludes as follows: 1. Metrorrhagia, following abortion or labor, should call for more prompt investigation, especially in women under thirty. 2. Dilatation and curetting, in such circumstances, is an operation of considerable responsibility, in view of the possibility of malignant disease. 3. Sharp curettes are contraindicated in the parturient uterus, and when septic infections exist. 4. All such curettings should be submitted to an expert pathologist for microscopic examination. 5. Continued metrorrhagia, after such treatment, should be regarded as of serious import, and should call for fresh investigation and prompt radical measures.

32. **Discussion on Appendicitis.**—The rather sensational discussion of appendicitis and muco-membranous typhlitis which had continued through several meetings of the Académie was closed July 3. Among the latest speakers Blanchard announced his conviction that intestinal worms are frequently responsible for these morbid conditions. They induce minute lesions in the mucosa of the intestine, and especially in the appendix, and bacteria soon ensconce themselves in the nests thus provided for them. In case signs of the presence of helminths are discovered, treatment should aim to expel them, both as a preventive of appendicitis and as a cure of existing intestinal trouble above or below. He related a number of instances in which symptoms indicated appendicitis, but after evacuation of a number of worms all symptoms subsided. He considers it the physician's duty to examine the stools for traces of worms, and if eggs of the trichocephalus, ascaris or oxyuris are discovered he advises giving three 1 gm. doses of thymol at one hour intervals on three successive days. These doses are as effectual as larger ones, and are useful for the ascaris and the oxyuris, as well as the trichocephalus. It is of the utmost importance that the patient should refrain from ingestion of alcohol, oil or other substances capable of dissolving the thymol and freeing its toxic properties. Vegetables fertilized with human excreta are liable to prove a prolific source for infecting man with helminths, and Blanchard urged the absolute prohibition of manuring with human excrements.

34. **Treatment of Opacity of the Cornea by Physical Agents.**—Sulzer is connected with the de Rothschild Ophthalmic Foundation and has been much pleased with the results of treatment of opacity of the cornea with electrolysis, with or without phototherapy, or the latter alone and radiotherapy. His experience includes 34 cases. Benefit was derived in all but 6, vision increasing considerably. The cases of interstitial sclerosis were improved as well as the more superficial cicatrices Applied directly on a superficial cicatrix the negative electrod with a current of from 4 to 7 milliamperes, leads to the forma tion of gaseous bullæ which lift up the opaque patch from th underlying tissues. The consequence is the formation of a mor translucent cicatrix, less white, less opaque, although th sclerosis may still persist. A much more intense reaction fo lows exposure of the eye to a bright light, rich in actinic ray the application lasting from 20 to 90 seconds, repeated in eigh or ten days. The results, Sulzer states, were particularl good in pronounced sclerosis, reducing the intraocular tensio and favoring the absorption of effusion in the papilla. Th only contraindication is a tendency to glaucoma. He has thu treated 24 patients, all but 4 under 20, with a single exposur for 6 eyes, 2 for 11, 3 for 17, and 4 or 5 for 2. In 14 cases th reaction to the light was very striking.

36. **Cancerous Tumors and Helminths.**—Borrel states tha among the rats and mice kept at the Paris Institut Pasteu those inhabiting certain cages presented a very much large proportion of spontaneous cancers than other animals, showin that there may be "cancer cages" as well as "cancer houses." The locality of the cancer also seemed to be decided by th special cage in which the animals were kept. One of thes cages has already furnished more than 30 cases of spontaneou cancer. In the lungs of animals which had succumbed to thes cancers, secondary tumors were found in the lungs wit helminths in the adjoining lung tissue. One rat, succumbin to an epithelial cancerous tumor in the right kidney, wa found to have cysts in the other kidney and the liver containin embryos of the *Tenia crassicola* of the cat. In another rat a large sarcoma of the liver was found surrounded by cysts exhibiting the same parasite. The sarcoma from this rat has been inoculated through three passages, suggesting that the cysticercus carries with it some virus yet unknown. This virus inoculated with the cells, in its passage from rat to rat, is capable, without any further intervention on the part of the helminth of propagating indefinitely the elements of the tumor. It is interesting further to note that in the two cases the cancer was of a different variety.

38. **Electric Mosquito Trap.**—Chaulin's apparatus is a sort of cylindrical lantern made of two large horizontal rings connected by vertical, parallel chains, rather close together, with a light inside. The electric current passes through the chains. Insects, especially mosquitoes, attracted by the light, can not pass between the chains without touching them in more than one place, thus closing the circuit and killing the insects by the charge of electricity that passes through them. Very little electricity is needed, a small storage battery taken temporarily from an automobile is ample for the purpose.

44. **Marie's New Views of Motor Aphasia.**—Marie's views were reviewed in an editorial in The Journal, Aug. 11, 1906, page 436. Dejerine energetically combats them and presents arguments to show the fallacy which has misled Marie. Dejerine's experience with hundreds of cases during the last 25 years makes him take an opposite view, which he here presents in detail.

49. **Composition of Ice.**—Sacerdote has found that as water freezes slowly all the impurities are pushed away from the part first freezing. The center of a cake of artificial ice is generally opaque, while the part first frozen—the outside—is generally clear. Whatever the character of the water used, the water obtained by melting the outer, clear parts, is almost perfectly pure, while that from the central, opaque part contains the impurities. The bacteria do not escape this law, he adds, but will be found congregated in the central part of the cake.

51. **Spinal Anesthesia.**—Freund reports experiences with 209 cases in which operations were performed under spinal anesthesia at Veit's clinic. This method of anesthesia has been proved to possess so many advantages and so few drawbacks that he thinks it has already won an assured position and possibly may take first rank among all methods of anesthesia, even for major operations. He used rather more of the anesthetic than others advise, and was particular to refrain from testing the patient's sensibility, believing that complete quiet is the best preliminary to an operation. If the analgesia is defective this is never due to the lack of receptivity on the part of the patient, he says, but to mechanical and anatomic conditions. The preferred point for the injection is as high as possible, at least between the second and third lumbar vertebræ, and exactly in the median line. The pelvis was always elevated immediately after the injection to an angle of 20 or 25 degrees from the horizontal, and kept in this position during the 20 minutes required for the local disinfection. When the laparotomy is commenced the pelvis is raised still higher. The anesthesia does not extend unnecessarily high with this technic. The extent of the anesthetized area can be further controlled by allowing more or less of the cerebrospinal fluid to escape. Four c.c. is the rule, and this is generally enough for gynecologic operations. There were 104 laparotomies and the spinal anesthesia was successful in 93; 30 Alexander-Adams operations, with success in 26; 16 vaginal operations, with successful anesthesia in 10; 48 vaginal operations, with anesthesia in 43—a total of successful spinal anesthesias in 181, that is, in 86.6 per cent. of 209 major gynecologic operations on women between the ages of 18 and 73. The remaining 13.4 per cent. required a little chloroform before the operation could be completed. One patient, an asthmatic woman of 73, with myoma of the uterus, 8 minutes after the injection, while the parts were being disinfected, the pelvis raised a little, rapidly died after vomiting and sudden arrest of the respiration. This fatality occurred in the early experience at the clinic, before the present technic was adopted, which ensures that the cannula does not enter too far. The guide is left in the cannula only until the skin and the first layer of the soft parts are passed. Then the guide is withdrawn and the cannula is cautiously pushed in until the cerebrospinal fluid flows out freely, and no farther. This ensures that the tip of the cannula does not go beyond the arachnoid space where are the sensory roots. These precautions had not been dreamed of at the time of the fatality reported, and it is highly probable that the cannula had been inserted too far, bringing the anesthetic to the motor roots, and paralyzing the higher vital centers when the pelvis was elevated. The few slight by-effects noted are growing constantly less with improved technic. Vomiting was observed in about a fourth of all the cases, but it is less and more transient than that liable to follow chloroform. More disagreeable is the brief paralysis of the anal sphincter with sudden passage of stools occasionally occurring after a vaginal operation. This he learned to obviate by the preliminary insertion of an opium suppository. He concludes with the statement that spinal anesthesia in its present form is eminently practicable.

60 *Bemærkninger om Forfrysning af det subkutane Fedtvaev. P. Koefoed.

59. **Primary Tuberculosis of Digestive Tract.**—This communication from the Copenhagen Institute of Pathologic Anatomy continues Fibiger's research on primary tuberculosis in the digestive tract. He found tuberculous lesions in 116 out of 213 cadavers, and in 13 they were primary in the digestive tract or connected glands. Among the 79 children, 25 were tuberculous, and in 4 of these the lesions were primary in the digestive tract. Ipsen has continued this research, the total material now comprising 600 autopsies. Tuberculous lesions were found in 311, and they were evidently primary in the digestive tract in 5.17 per cent. of the total cadavers, and in 10 per cent. of the tuberculous, that is, in 31 cadavers. Out of the 187 children's cadavers, 58 proved to be tuberculous, and the lesions were primary in the digestive tract in 10, that is, in 17 per cent. These figures are manifestly too low, as they do not include those in which the tubercle bacilli passed through the intestinal walls without leaving any traces. The circumstances indicated infection from cow's milk in some of the cases, and from association with consumptives in others.

60. **Freezing of Subcutaneous Adipose Tissue.**—Koefoed describes a case in which the excessive use of an ice bag for threatened appendicitis froze the subcutaneous fat. The patient was an extremely nervous young woman, and when first seen in consultation she was somewhat feverish and agitated. She complained of pains in the ileocecal region, where there were indications of the erythem that follows freezing. The deep subcutaneous fat was infiltrated and hard as from a typical phlegmon. An incision failed to reveal any pus, but the subcutaneous tissue was hard and grayish in color, and it did not bleed. The skin bled normally during the incision. Only the lowest vascularized stratum presented a normal aspect. In the course of 2 weeks everything had returned to normal, without any suppuration or sloughing. Koefoed had a similar experience with another patient, whose family physician had likewise applied the traditional ice bag. The changes in the subcutaneous tissue persisted for 2 and 3 weeks in these cases after the fat had been so thoroughly frozen. This possibly occurs oftener than is generally supposed, and may be the unrecognized cause of certain complications.

61. **Death in Diphtheria.**—Fischer has been studying the causes of death in 287 cases of fatal diphtheria. Only about 25 per cent. of the patients succumbed to general diphtheric intoxication, and a little less than 25 per cent. to tardy paralysis. All the others—more than 50 per cent.—died in consequence of pulmonary lesions. The latter was the cause of death in all the infants and in 83 of the 139 cases in children between 1 and 3, and in 16 of the 85 cases in children from 4 to 10, which included also 33 cases of fatal tardy paralysis. The 17 fatal cases of diphtheria in patients over 10 included 9 deaths from early general intoxication, 3 from tardy paralysis, and 3 from tardy sepsis. He remarks that far too little attention has been paid hitherto to secondary infection in diphtheria, and yet its importance as a factor in the fatal termination is emphasized by the above figures. Diphtheria antitoxin had been administered in every case. He is convinced that the only way to bring the diphtheria mortality actually under control is to supplement the diphtheria antitoxin with an effectual antistreptococcus and antistaphylococcus serum.

62. **When to Operate for Uterine Myoma.**—Essen-Möller's practice is never to operate so long as the myoma does not cause symptoms. But he keeps the patient under observation, and examines from time to time, ready to operate at the first indication of hemorrhage, rapid growth, or the like. He has applied these principles in 111 cases, with highly satisfactory results, as he describes in detail.

63. **Drainage After Laparotomies.**—Westermark relates his experiences with drainage as he applied it in 6 out of 272 abdominal operations. None of the rest had any drainage. He follows Mikulicz' technic for peritoneal drainage, and restricts its application exclusively to cases in which pus in the small pelvis has contaminated the field of operation, or when the virulence of the pus is unknown. Also when the intestines or bladder have been injured and pus is found, and also in all cases of lesions of the large intestine, even when there is no suppuration. He thinks that his results indicate the advantage of restricting drainage to these conditions.

65. **Gastrointestinal Disturbances Due to Arteriosclerosis.**—Rodhe describes a case of arteriosclerosis in a man of 65 in whom severe pains developed in the epigastric region, accompanied by palpitation of the heart and difficulty in breathing. A common cause for the heart and stomach troubles was suggested by the lack of any other symptoms from the digestive tract, and the absence of any signs of nervous or hysteric tendencies, but chiefly by the promptly successful result of treatment. No gastralgia of any other origin yields at once to heart tonics. Digitalis and potassium iodid were ordered in small doses, with a suitable diet. In another case a man of 65 with generalized arteriosclerosis complained of attacks of pain in the abdomen at times during the last few years. As in the first case the absence of signs of neurasthenia or hysteria and of digestive disturbances, and the prompt benefit from heart tonics, are presumptive evidence in favor of the theory that the painful attacks are due to the existing arteriosclerosis. The cases in which the attacks of pain occur alone, that is, unaccompanied by angina pectoris, are the most important from the differential standpoint. If the true cause is not recognized, the patient loses the benefit of appropriate treatment. The most characteristic feature is the strict localization of the pain in the epigastrium, appearing in persons of 40 or over. The pain is a sharp, stabbing or burning sensation, lasting generally only for a few minutes. It radiates sometimes to the liver, shoulder or arms, and ptyalism may be observed with a cold sweat and semi-unconsciousness. Between the attacks there is no pain, at least in the milder cases; in others there may be a dull, continuous ache. There are generally no other disturbances from the digestive tract, although sometimes constipation, diarrhea, meteorism, etc., may be observed. Other morbid processes are liable to occur in the digestive organs aside from those due to the arteriosclerosis, of course, and the latter may induce thrombosis, or even actual ulcer formation. The attacks in Rodhe's cases followed unusual physical exertion. Buch has reported a case in which the attacks were liable to come on when the patient lay down. Emotions and excesses are also liable to bring on an attack. On the other hand, the kind of food has no influence. The shortness of the painful attack, the radiation of the pains, and the occasional alternation with angina pectoris confirm the diagnosis. The same causes that elicit angina pectoris are noted in the history of these attacks. Pressure on the epigastrium sometimes induces pain similar to that of the typical attack. The pure arteriosclerotic gastralgia subsides or vanishes altogether under diuretics, digitalis or strophanthus. The syndrome may simulate ulcer, nervous dyspepsia or even cholelithiasis, until death in syncope occurs, and autopsy reveals the unsuspected sclerosis of the coronary, stomach, or intestinal arteries. Jaworsky has published reports of 4 such cases in which the patients suddenly succumbed to this form of arteriosclerosis while under treatment at Carlsbad for nervous dyspepsia.

66. **Operations for Nephritis.**—Ekehorn gives the details of 2 cases of acute infectious nephritis and of 4 of renal hematuria in chronic nephritis. He also analyzes an extensive list of articles on this subject. His conclusions are that hemorrhage from the kidney is not the prerogative of any special form of nephritis. It is much more likely to be the work of the toxic influences causing the nephritis rather than of the nephritis itself. He operated in all his cases and the operation always put an end to the hemorrhage. He discusses the question of why excessive pressure in the kidney induces hemorrhage, while nothing analogous occurs in other organs, and why an incision, relieving the pressure, arrests the hemorrhage. The purely mechanical influence of the altered position, adhesion to adjacent organs, pressure, etc., must not be underestimated, he remarks. Rovsing seems to be the only one who has given due consideration to the mechanical factor in renal hematuria.

73. **Influence of Modern Hygiene on Cities.**—Lindman gives a number of diagrams showing and comparing the amount and nature of the sickness and the mortality in 10 cities in Sweden during the last 30 years. The general mortality has dropped from 250 to 152 per 10,000 inhabitants. The decline has been most pronounced in the acute infectious diseases and diarrhea, also in nervous and pulmonary affections, while on the other hand the number of deaths from affections of the heart and vascular systems have increased, and the number of fatal puerperal affections averages nearly the same.

74. **Old Tuberculin as a Therapeutic Measure.**—Tillman relates his experience with 7 cases of phthisis in which he used Koch's old tuberculin. It was given in a subcutaneous, infrascapular injection, twice a week, and the patients afterward lay down for a time. They had all had a preceding course of sanatorium treatment and the disease was of 2 years' standing at least. Some were in an advanced stage, but improvement was manifest in all, especially after suspension for a time.

77. **Primary Aspergillosis of the Lungs.**—Baccarani describes 3 cases, all occurring in one family, the patients ranging in age from 9 to 19 years. There were no known predisposing factors in these cases, 2 of which terminated fatally. The course of the affection was extremely rapid, suggesting fulminating typhoid in some respects. One patient, a girl, died of hemoptysis a month after the first symptoms, and another girl succumbed to progressive marasmus in 40 days. The youngest child. a boy, was treated with arsenic and iodid at the first symptoms, two weeks after the death of his second sister; at the same time the house was thoroughly disinfected. In 2 weeks the boy had completely recovered. The rapid emaciation in the fatal cases was more striking than Baccarani has ever witnessed in any other affection.

79. **Postoperative Icterus.**—Four typical cases are described by Campora. The operation was fixation of a wandering kidney in one and bilateral inguinal herniotomy in the others. There was no appreciable hemorrhage in any case. The icterus was probably of toxic origin, due to the action of the chloroform on a predisposed liver. Three of the the patients were alcoholics and one of these succumbed with intense icterus. edema, subdelirium, and coma. The others recovered.

80. **Glycogen in the Liver.**—Massari mounts in paraffin the sections of the liver to be examined, and treats them with a mucilaginous solution of iodin for examination under the microscope. The granules of glycogen show plainly with this technic at an enlargement of 47 diameters, and their distribution can be instructively studied at 297 diameters. The findings by this microchemical technic amply confirm the importance of the presence of glycogen in differentiating slow from sudden death. Also the important effect of putrefaction in causing the glycogen to vanish. In case of death from intoxication with illuminating gas, the proportion of glycogen in the liver cell is enormous in comparison with that found in other cases of deaths from violence or accident. No glycogen is found in case of acute and chronic phosphorus poisoning. In acute arsenic poisoning traces of glycogen are apparent, but not in the chronic cases. It is abundant in acute poisoning from corrosive sublimate, and traces are apparent in the chronic cases. The glycogen vanishes exceptionally slowly in case of putrefaction after poisoning with illuminating gas. Control chemical tests confirmed the accuracy of the microchemical findings.

82. **Pathogenesis of Asthma.**—Gualdrini thinks that nervous factors play a large part in the origin of asthma in some cases, and here relates 3 typical examples. The asthma came on each time without any appreciable cause aside from emotional stress on neuropathic antecedents.

83. **Percussion Findings with Enlargement of the Heart.**—Pollaci says that dulness over the body of the sternum is frequently an important sign of enlargement of the right heart. It is especially valuable when the breasts are so well developed that it is hard to trace the right outline of the relative cardiac dulness. He describes the mechanism and reasons for the changes in the percussion findings over the sternum under these conditions.

84. **Epithelioma of the Lip.**—Serafini's experience with 100 cases of epithelioma of the lip has shown that the glands become involved in two or three months, but that radical resection of tumor and glands is followed by a complete cure in 73 per cent. of the cases. Recurrence is generally observed within six months. Eight years elapsed in one of his cases, and he is inclined to regard this as rather a new growth than a recurrence after such a long interval. In 24 cases the recurrence was on the lip, and in 17 in the submaxillary region. Advanced age does not affect the results of operative treatment unfavorably. Even in case of repeated recurrence, the results may finally be a complete cure. All but 14 of his patients were men. They succumbed generally at last to some respiratory affection after the successful removal of the cancer.

85. **Test for Arsenic, Phosphorus and Antimony.**—Pedrazzini has modified slightly the Gutzeit test so that it can serve to differentiate intoxication from arsenic, phosphorus and antimony. A little of the substance to be examined is placed in a test tube with some sulphuric acid and a scrap of zinc (free from arsenic). A crystal of silver nitrate is placed on top of a disc of filtering paper laid over the mouth of the test tube. In case of the presence of arsenic, a gas is generated which turns the silver nitrate yellow or black. The same reaction occurs also with phosphorus and with antimony. These substances can be excluded and the findings limited to arsenic by using a solution of silver nitrate instead of the crystals. A bent tube conducts the gas from the first test tube into a second test tube containing the silver solution. When the gas generation is finished, the silver solution is filtered and the Gutzeit test is then applied to the filtrate with the solid silver nitrate as above. Phosphorus can be detected with the same technic, estimating the phosphoric acid with uranium, or potassium acetate. Antimony is revealed by washing the filtrate with a solution of tartaric acid treated with dilute hydrochloric acid. Trichlorid of antimony results, and, treated with hydrogen sulphid, an orange precipitate is thrown down.

86. **Spirochetes Inside the Cells in Syphilis.**—Bandi calls attention anew to the importance of the accumulations of spirochetes inside the cells. It is not a phagocytic process, as the spirochetes seem to be intact while the cell seems to have suffered. He believes that the condition indicates actual vital parasitism of the cell.

87. **Artificial Production of Leucocytosis in Peritoneal Infection.**—Diez has been experimenting with nucleic acid as a means of enhancing the vital resistance of the peritoneum to infection. The results were all extremely favorable, both in his experimental and clinical research. He advocates, therefore, injection of a 2 per cent. solution of nucleic acid as a preliminary to abdominal operations and also a few hours after perforation of the stomach or intestine.

89. **Surgery of the Lungs.**—Skultecki sutured the lung after a serious stab wound, and the patient suffered long from various mishaps resulting from infection of the deep lung tissue. This case and others in his experience have convinced him of the inadvisability of attempting to suture a stab wound of the lung. Immediate aseptic occlusion is the best technic, he believes.

90. **Veratrum Viride in Case of Increased Arterial Tension.**—Pesci tabulates the details of 19 cases to show the value of veratrum viride in reducing exaggerated arterial tension. He believes that it acts by soothing the heart and dilating the arteries. The indications as he formulates them are: 1, Chronic nephritis, in which it serves to prevent and to combat uremia and to postpone asystolia; 2. lead poisoning, in which it acts on the colics probably due to spasm of the splanchnic arteries; and, 3, the early stages of arteriosclerosis, in which it reduces the pressure and retards the progress of the affection. His dosage is .25 c.c. subcutaneously in uremic attacks, repeating the dose at half-hour intervals. In case of

nephritic hypertension with dyspnea or in lead colic, he gives from 20 to 30 and 50 drops in the 24 hours, keeping the drug up for 5 or 6 days. In hypertension from any cause he gives from 15 to 30 drops a day for nearly a week. He believes in suspending the drug for a few days and then resuming it. The above dosage refers to the fluidextract; he doubles the doses for the tincture. Of course the best results follow when the walls of the arteries are still capable of enlarging. In case they have lost their elasticity, then drugs are preferable which act on the blood, rendering it more fluid, or on the kidneys, promoting diuresis, or promoting the metabolism, like iodin. An appropriate diet is all-important, and should be maintained for months.

91. **Sensitive Test for Albumin in Urine.**—Tognetti describes the research which resulted in what he calls the "tanno-hydrochloric" test, which reveals albumin even in a proportion of 1 to 200,000. The advantages of tannic acid as a reagent for albumin have long been known, but it could not be used in urine as other ingredients of the urine also give a positive response. He has removed this difficulty by adopting the following technic, which, he says, renders the test reliable, instructive and extremely sensitive. He adds to the urine an equal amount of an alcoholic solution of tannin (1.5 gm. of tannin in 100 c.c. of 90 per cent. alcohol). The whole is then heated and an equal quantity of a 33 per cent. aqueous solution of hydrochloric acid is added—equal to the quantity of urine. In the presence of albumin the fluid becomes opaque and the albumin is gradually thrown down in a yellowish-white precipitate. In case of icterus, the bile pigments must first be removed by the Grocco technic, that is, by adding glacial acetic acid in the proportion of one-thirtieth or one-fiftieth of the amount of the urine. With the exception of this precaution, which is necessary with other tests for albumin, the tanno-hydrochloric test, he declares, can be regarded as free from causes of error. The combination of tannic acid, hydrochloric acid, alcohol and heat eliminates the usual drawbacks of tests for albumin.

92. **Action of Radium in Rabies.**—Tizzoni here mentions that he has been successful in saving 50 animals (rabbits) by means of radium after inoculation with rabies, which otherwise would have been fatal. Some of the rabbits have been under observation for more than a year. The curative and preventive effects of the radium were constant and directly proportional to the extent of the exposures. There is a remarkable lack of proportion, however, between the number of radioactive units in the specimen of radium and the curative effects observed, the smaller specimens being nearly as powerful as those five times larger. This shows that small amounts can be used in the clinic, free from the least dangerous tendency. This article is a reply to those who have contradicted his assertions. His latest researches, he says, only confirm his first announcements.

94. **Implantation of a Muscle to Repair a Defect in a Long Bone.**—Morelli describes a case in which he aided the healing of a rebellious osteomyelitic process and large defect by implanting part of a muscle. The cavity was in the humerus and after curetting he implanted part of the deltoid muscle, holding it in place with a few sutures. Healing was remarkably prompt and complete, and he recommends general adoption of this method of repairing a defect. Part of the belly of the muscle can be easily utilized and the procedure does not affect the functions of the muscle in the least. He is now conducting experimental research to learn the mechanism of repair afterward.

95. **Toxins Destructive of Larvæ.**—Bongiovanni has been studying the sudden destruction of the larvæ of the malaria mosquitoes which is sometimes observed in certain pools of standing water. He announces that it is the result of the action of toxins generated by a bacillus and streptobacillus, which he found constantly in such waters. These larvicidal toxins are not produced unless the water reaches a temperature of from 30 to 34 C.

96. **Diagnosis and Prognosis of Acute Cerebral Affections.**—Riva-Rocci analyzes 31 cases observed during the last 5 years and discusses the various differential points. He remarks in regard to the prognosis that in case of concussion of the brain the immediate prognosis is rather favorable, while the later should be guarded. In cerebral embolism, the prognosis depends on the heart and condition of the arteries and on the nature of the lesion. Syphilitic lesions are easily influenced by treatment, but the ultimate outcome has been worse in his experience than with lesions of other origin. The prognosis in encephalitis depends on the nature of the disease germ and the operability of the lesions.

98. **Stomach Functions After Splenectomy.**—In the case described the stomach functioning had not been specially examined before the removal of the spleen, but afterward it was found exceptionally perfect. The digestive functions were performed with rare perfection.

101. **Mercury, Etc., in Relation to Tests for "Occult Blood."**—Guyot applied the guaiac or aloin test for "occult blood" in the feces after administration of mercury, iron or other metallic drug. When large doses of mercury had been given the findings were occasionally positive. He ascribes this to the bile secreted in exceptional amounts under the influence of the cholagogue. The same results were obtained when cholagogues other than mercury were given (podophyllin or rhubarb).

103. **Action of Radium in Rabies.**—Calabrese's control research, he states, has entirely failed to sustain Tizzoni's announcements in regard to the curative or preventive action of radium in rabies. Calabrese's results were invariably negative

NEW PATENTS.

Recent patents of interest to physicians:

827066	Therapeutic match. Augustus P. Hafner, New York.
826659	Apparatus for automatically signaling the presence of deleterious gases in the atmosphere. Henri Hauger, Paris, France.
826949	Combination carton and gauze cap. Charles R. Lindsay, Jr., Chicago.
826685	Medical irrigator. John A. Noble, San Francisco.
827030	Sanitary house. Edward J. Noblett, Chicago.
826881	Catamenial sack. David A. Powdermaker, Philadelphia.
826805	Invalids' folding table. John Scheibner, Beaver Falls, Pa.
826614	Making hydrochloric acid and calcium carbid. William H. Seamon, El Paso, Texas.
826699	Diastatic substance and making same. Jokichi Takamine, New York.
826978	Combined invalid and surgical couch. Virginia Whittington, Valdosta, Ga.
826813	Artificial leg. Chester B. Winn, Buffalo, N. Y.
826815	Suspensory bandage. Henry J. Wortz, Philadelphia.
827207	Suspensory bandage and dressing retainer. Joseph L. Boehm, St. Louis.
827610	Washing and disinfecting apparatus. Joseph G. Branch, St. Louis.
827420	Making hydrosulfite solutions. Philip S. Clarkson, Beverly, N. J.
827092	Sanitary disinfecting and deodorizing block. Joseph T. Freestone, Rock Ferry, England.
827099	Medical device. Frederick Hofmann, New York.
827693	Hypodermic syringe. Frederick W. Korb, Cleveland, Ohio.
827162	Sanitary device for closets. Albert F. Lesler, New York.
827645	Ear-trumpet. Christopher W. Levalley, Milwaukee, Wis.
827383	Aseptic syringe. Patrick J. McElroy, Cambridge, and W. A. Randall, Swampscott, Mass.
827387	Apparatus for mounting and cooling statical ozonizers. Marius Otto, Paris, France.
827396	Sterilizer and pasteurizer. Sam G. Scanlan, Madison, Wis.
827399	and 827400 Apparatus for purifying and softening water. S. L. Sheuerman and J. F. Hand, Des Moines, Iowa.
827193	Surgical instrument. George Thrash, Hominy, N. C.
827133	Massage instrument. Irving A. Weston, Syracuse, N. Y.
828178	Bed-pan. Adele E. Betts, Kensington, Md.
828268	Making sulfur trioxid. Henry S. Blackmore, Mount Vernon, N. Y.
828022	Truss. Samuel A. Donnelly, Chicago.
827720	Artificial leg. Wm. E. Irwin, Yorkville, S. C.
827721	Producing salts of oxyacids of chlorin. Arthur E. Gibbs, Niagara Falls, N. Y.
827910	Apparatus for administering liquid anesthetics. John A. Hollenberger, Hagerstown, Md.
828221	Exercising apparatus for correcting deformities. Franz Langel, Cologne, Germany.
828292	Pocket audiphone. Eugene W. Schneider, New York.
828146	Forceps. James Somers, San Juan, Cal.
827896	Micrographic microscope. Otto H. F. Vollbehr, Halensee, near Berlin, Germany.
828007	Operating table. John D. Williams, Lewisville, N. C.
828809	Belt attachment for sanitary supports. Jennie L. Bornstein, Dayton, Ohio.
828722	Atomizer and like instrument. Frank C. Dorment, Kalamazoo, Mich.
828733	Cabinent for treating diseases by light. B. F. Fuller, El Reno, Okla.
828311	Vaccine shield. Christian Heidemann, St. Louis.
828651	Suspensory. Max B. Hirsch, Chicago.
828611	Capsule filling machine. Jasper F. Kobler, Niagara Falls, N. Y.
828754	Bed-pan. John Lopitsch and F. Naumann, Green Bay, Wis.

Address

THE ART OF MEDICINE.*

EDWARD HORNIBROOK, M.D.
CHEROKEE, IOWA.

Almost all the phases of medical thought are so thoroughly discussed in the books of specialists and in the periodical press that the general practitioner who has neither time nor opportunity to pursue new lines of investigation finds difficulty in selecting a theme which will not be already familiar to the members of this learned society. I have, therefore, chosen a subject which may invite criticism and which shall be suggestive, even if not instructive. Is the art of medicine improving? This question would be answered affirmatively, at first thought, by the majority of physicians. Yet there are many thoughtful men who, while admitting that scientific medicine has made wonderful progress during the last half century, are still constrained to believe that the Art as distinguished from the Science has deteriorated.

SCIENTIFIC RESEARCH AND MEDICAL PROGRESS.

Until recently the path of medical investigation might be compared to a plateau without obstructions, where the wheels of progress were unimpeded and where progression, though rapid, was often in a circle, ending where it began, or so near it that actual advancement was scarcely discernible. It is obvious that in the cycles of the ages substantial gains have been secured. In recent years the growth of the sciences has been so luxuriant that achievement has been slow, sometimes impeded and always laborious.

Isolated facts in biology, histology, chemistry and bacteriology have been collected with such industry and rapidity that an attempt to classify them and to draw practical conclusions causes discouragement and leaves the mind in doubt and uncertainty.

The medical journals teem with discussions of scientific subjects and devote little space to matters pertaining to the treatment and cure of disease. One who would venture to say that he did not believe in the germ theory of disease would be considered as an archaist, and yet none of us believe that a germ is the etiologic factor in all diseases. There are comparatively few maladies in which the specific germ has been isolated, and, therefore, our boasted scientific progress has only shed light on a few of the problems which daily claim our attention. Most of our useful knowledge has been gained from the accumulated experience of our ancestors and contemporaries and not from modern research.

What is disease? The Century Dictionary gives this definition: "A marked, painful or otherwise distressing physical condition, acute or chronic, which may result either in death or in a more or less complete return to health; deviation from the healthy or normal condition of any of the functions or tissues of the body."

What we know about disease of the nervous system has been chiefly acquired by close observation of the clinical symptoms, aided by scientific methods of investigation. Disorders of the chylopoietic viscera manifest themselves by their syndrome, and do not readily yield their secrets to microscopic, bacteriologic or *x*-ray investigation. The pathologic conditions resulting from disorders of the ductless glands may be studied scientifically, but such study has hitherto shed little light on their etiology or treatment. Skin diseases come in the same category, except the few of parasitic origin. Functional derangements elude instruments of precision and often baffle the experienced physician.

For preventive medicine scientific reasearch has done much; for the art of medicine the triumphs of modern investigation are limited. Eliminate diphtheria antitoxin and perhaps antitetanic serum and the other remedial agents which have been used on account of the discovery of specific germs are of questionable utility. When germs are known to be the etiologic factor, science and common sense have suggested methods more or less successful for preventing their entrance and for neutralizing the effects of the toxins which they produce. So far as we are enabled successfully to accomplish these objects, we acknowledge that science has blazed the way for our guidance, but she has contributed nothing which has shortened the duration or lessened the morbidity of scarlet fever, measles, whooping cough, influenza, typhoid fever, etc. What vaccination has done for smallpox is the result of observation and experience, not the result of the discovery of scientific facts or their application to the prevention or cure of disease.

Therefore, I question the wisdom of so framing the curricula of medical colleges that a large part of the time which might profitably be spent in the study of the symptomatology of diseases and perverted functions is devoted to a study of the multiform and varied appearance of germs, which as yet have been proved to be the cause of but few of the maladies which affect humanity.

For the treatment of these distempers accumulated experience is our only reliable guide; and the time which should be given to appropriating this experience is devoted to bacillus hunting or to that which yields infinitesimal results in enabling the student to battle with the many problems which will engage his attention in practice. What use can be made of the physician's knowledge of *Staphylococci*, *Streptococci* or *B. pyocyaneus* in his diagnosis or treatment of neurasthenia, hysteria or neuritis? What benefit will the various theories of immunity be to him or his patient in making a differential diagnosis between gastric ulceration and cholelithiasis? How can he apply his theories of phagocytosis in differentiating mitral insufficiency from aortic regurgitation?

---

* Oration on Medicine before the Iowa State Medical Society.

The study of the side chains of immunity is interesting, but it affords no assistance in distinguishing one from another the numerous family of skin diseases. Scientific research has done little to elucidate the disorders of the special senses, and less to enable us to understand the pathologic changes which affect mentality. How mental states affect bodily functions and how physical conditions react on mental processes seems to be beyond the pale of science, and yet how perplexing are the problems which they present for our consideration. Until we understand the force evolved in procreation, science will grope in the dark when grappling with cellular or nervous dyscrasiæ. Until we know something of the mind, or until it can be shown that it has a material organism discernible by the physical senses, science will avail nothing in elucidating the influence of mind over matter.

No analyst or synthetist has yet succeeded in bringing within our purview the nature of the force generated by impregnating the female germ or discovered the potentiality thus inaugurated which starts the cellular multiplication necessary to produce the perfect plant or animal. No instrument of precision, however great its power, and no form of light, electrical or chemical, has enabled us to observe or detect the elements of which thought is composed. We can observe the phenomena which both life and mind exhibit, but we do not understand what they are. The physical effects which life and mind produce may be learned by observation and experience, not by test tube, crucible, *x*-ray or microscope.

The conclusion is, therefore, inevitable that much of the progress in the art of medicine must come from close observation as well as from the meritorious and painstaking work of the pure scientist.

PROVINCE OF SCIENTIFIC RESEARCH.

Let me be not misunderstood. I do not disparage the aid which the collateral sciences have contributed to medical advancement. Research has done much to explain the reasons for the effect of the means which had been used empirically in the treatment of disease. Science has shed light on problems which were unsolvable before modern methods of investigation were introduced; but she has not supplanted the knowledge gained through centuries of experience.

In my opinion, her province is to aid, elucidate and explain, but not to set aside what has already been established. For example, the beneficent effects of vaccination were proven before any theory of immunity was exploited. Quinin had long been employed and its uses well understood before the *Plasmodium malariæ* was discovered. Iodin was used to arrest suppuration before the pus-producing cocci or bacilli had been thought of and before the words toxemia and intoxication found a place in medical nomenclature.

My contention is not that the sciences should be studied less, but that symptomatology and therapeutics should be studied more, so that instead of waiting for the proofs and demonstrations of science our art may be promptly used for the arrest and cure of even the diseases in which the microbe has been proven to be the etiologic factor.

> "Science still stops to reason and explain,
> Art claps the finger on the bleeding vein."

Our diagnosis is made from subjective and objective symptoms in 95 per cent. of our cases, and when scientific methods are invoked they generally confirm the conclusions reached by the old, reliable methods. To delay action until our opinions are confirmed by the scientists often causes us to lose the golden opportunity for combating and arresting disease. The symptoms of diphtheria are so pronounced that deferring treatment and not enforcing quarantine until a return can be obtained from the state bacteriologist is so fraught with danger that it might be characterized as criminal negligence. If in typhoid fever the proper dietetic and hygienic methods are not enforced until proof is afforded by the agglutination test or finding the bacillus, the mortality of the disease will be greatly increased.

The best results in the treatment of pulmonary tuberculosis are obtained when treatment is instituted before the bacillus has made its appearance, and this treatment should not be abandoned or relaxed even when the microscope negatives the diagnosis based on subjective symptoms and the knowledge gained by percussion and auscultation. During the last six months I succeeded in restoring a patient to health in whom a learned physician denied the existence of consumption, because he could find no bacilli. I have seen a patient die of tuberculosis within the last year when frequent examinations by the state bacteriologists gave negative results. I experienced the greatest sorrow of my life because two competent bacteriologists gave negative reports in my daughter's illness. I had diagnosed consumption; but, accepting the dictum of the time, "No bacilli, no tuberculosis," my efforts were relaxed and mourning and sorrow followed.

From these facts and hundreds of others which could be adduced it is obvious, I think, that it is better for the physician and safer for the patient to rely on the evidence gained by close observation, trained special senses and accurate knowledge of the symptoms of disease than to pin his faith solely to the revelations of the test tube, the *x*-ray or the microscope. These last have their uses in confirming opinions already formed or in causing us to reject opinions based on insufficient evidence, but they should not supplant the old and long-tried methods of investigation.

The tendency of the age is to extol the new and decry the old. A new fad or fancy propounded in a modern postgraduate school is seized with avidity, and too often influences practice to the detriment of the patient and the injury of the profession. As proof of this I might instance the indiscriminate use of the coal-tar preparations in recent times. I have seen them used with fatal effects in pneumonia, typhoid fever, smallpox, measles, diphtheria and septicemia.

IS THE ART OF MEDICINE DECLINING?

The practice of medicine is but the exercise of common sense, educated by acquisition of the learning and experience of our predecessors, fostered and strengthened, but not displaced, by modern methods. A knowledge of the functions of all the organs of the body is the first requisite. A knowledge of their derangements is the second, and a knowledge of the best methods of restoring them to their normal condition is the third and last, but not the least, in importance. Is our art improving or declining in that last most important particular?

I am saved from the necessity of answering this question by the timely publication of an address by Dr.

Billings[1] and the symposium on the proprietary medicine and the nostrum evil before the Chicago Medical Society.[2] To these articles I would direct the attention of all who are practicing medicine and prescribing remedies not in accordance with the teachings of the standard works on therapeutics and the directions of the Pharmacopeia, but in accordance with the literature supplied by the manufacturing chemists and the wise (?) and confident instructions of their traveling salesmen. Wisdom and experience which has not been gathered within the last decade is seldom accredited. Unless the views of the great authorities, like Watson, Austen Flint, Sr., Sir Astley Cooper or Valentine Mott, are reinforced by the teachings of some postgraduate professor or other evanescent luminary, their great names would soon pass into oblivion. The commercial instinct of some manufacturer might save them from such a fate by attaching their names to the recommendation of a nostrum or to a "patent medicine" advertisement. This growing disposition to ignore experience, together with the modern craze for bacillus hunting, and the manifest ambition of so many young practitioners to become great surgeons, even when they could not differentiate a dermatitis from smallpox, or measles from chickenpox, are, I think, among the causes which lead so good an authority as Sir Dyce Duckworth to say: "The art of medicine is fast declining."

The Incompetent Diagnostician.—This opinion is incidentally confirmed by Dr. Frank Billings,[1] of Chicago, who says:

> A large number of the medical profession do not practice medicine rationally. They have no clear conception of disease process. They do not study and examine the patients. No diagnosis is made at all or only from subjective conditions. Symptoms are treated. Headache, backache, indigestion, albuminuria, cough, constipation, dysmenorrhea, insomnia, nausea, dyspnea, etc., all call for drugs with no attempt to get at underlying causes.

This unscientific, not to say irrational, tendency is fostered, if not engendered, by the vast number of nostrums "strictly ethical" advertised extensively in medical journals and forced on the attention of the profession daily by those who make their living and the fortunes of their employers out of our credulity. Thus, we have headache tablets, cystitis tablets, gonorrhea tablets, dyspepsia tablets, heart tonics, liver tonics, etc., etc., besides medicines with the many uses of Frelich's tonic, for instance, which is advertised to cure "paralysis, vertigo, epilepsy, Bright's disease (early stages), neurasthenia, debilitating losses, mental failure, spinal weakness, nervous dyspepsia, all trouble affecting the brain nerve centers and spinal cord, and as a safe and powerful aphrodisiac." These specifics or antidotes to so many diseases are, I fear, becoming antidotes to thought and reasoning and observation, which are the essential qualifications of the medical practitioner.

LOSS OF LOVE AND ESTEEM OF PATIENTS.

The art of medicine is, I think, declining also in the very essential element of winning and holding the love and esteem of our patients. Without this love and esteem we can not exert the psychical influence so essential in sustaining the hopefulness and fortitude of the suffering and afflicted. An important function of the family physician is to amuse and support the spirits and hopefulness of the patient, so as to give Nature the best opportunity for curing the disease.

It is unlikely, I think, that the waning affection of the people for their family physician is caused by the want of assiduity or the lack of interest of the medical attendant. No one except the patient and his family is so deeply interested as the physician. No one gives the thought and endures the anxiety which he does; and yet it can not be denied that the gratitude and affection which he once received is not given with the ungrudging generosity with which it is given to the trained nurse. The payment of the fee, or the refusal to pay, discharges the obligation to the physician, and gratitude, if any is bestowed, assumes the form of a "lively sense of benefits to come."

The best years of his life may be given in the most self-sacrificing manner to the service of the people of any community and his departure will bring no manifestations of appreciation. His skill and motives may be questioned by those he has benefited, without their being told, in the words of Whitcomb Riley, that they are "the most ungratefull'est of men." The oldest and most painstaking physician may die and there will be no general manifestations of sorrow to equal that described by Will Carleton:

There's a gathering in the village, that has never been outdone
Since the soldiers took their muskets to the war of '61;
And a lot of lumber wagons near the church up on the hill,
And a lot of country people, Sunday-dressed and very still.

. . . . . .

But perhaps it still is better that his busy life is done;
He has seen old views and patients disappearing, one by one;
He has learned that death is master both of Science and of Art;
He has done his duty fairly, and has acted out his part.

And the strong old country doctor,
And the weak old country doctor,
Is entitled to a furlough for his brain and for his heart.

What are the causes for this waning affection? Is it that we fail to bring the philanthropic aspect of our labors before the notice of the public? We do not parade our philanthropy, but let a great calamity, like the San Francisco horror or even the Pomeroy cyclone, come on us and the services of the whole profession will be given gratuitously. Is it not possible that the personal services which we once rendered and which are now relegated to the trained nurse had much to do with cementing the bonds of friendship between ourselves and our patients?

Perhaps our devotion to science and our desire to ascertain the cause of suffering lead the friends to surmise that our interest is greater after the death of their loved ones than it was before. It may be that our delay in reaching conclusions and not applying remedies until we have exhausted the resources of science in discovering the cause of the symptoms leads them to think that we are more interested in the scientific aspect of the case than we are in the welfare of the patient.

However this may be, let us remember that our mission is to save life when possible, prolong it when we can, and, if we can not cure, to alleviate pain and suffering, to "soothe the pillow of the dying and smooth the pathway to the grave."

"This be our task; Henceforth our path is straight,
Wherever anguish is, or grief, or pain
There be our places; Then let us do our part,
Striving to antidote death's deadly bane
By our divine and ever-blessed Art."

Treatment of Obesity.—P. H. Sunde, Los Angeles, in the *Southern California Practitioner*, declares that to give medicines in obesity and to disregard the diet and other modes of living, is simply ridiculous. Medicines at best, he states, must only be regarded as secondary measures.

Original Articles

THE DIETETICS OF OBESITY.*

ALFRED C. CROFTAN, M.D.
CHICAGO.

The reduction of obesity is an important therapeutic task, not so much when considered in the light of a tribute to the vanity of the afflicted, but when regarded as a necessary step toward removing adipose tissue that is producing disagreeable or dangerous complications about important organs, notably the heart and arteries, the bronchi, the digestive apparatus and the nervous system. It will often be found that these complications only disappear when the fat is reduced. We see here similar conditions as in diabetes, where, too, many of the complications rapidly disappear when the sugar is reduced; whereas in diabetes, however, the causes that determine these complications are chemical, in obesity they are mechanical in character.

The methods at our disposal for reducing obesity are chiefly dietetic. Second in importance is the regulation of the muscular exercise. These two means, singly or combined, usually suffice to accomplish the desired purpose, for with a decrease of the intake of fat-forming pabulum and an increase of its destruction by exercise the fat content of the body must needs dwindle. These measures may, to advantage, be enforced by certain hydrotherapeutic and medicinal means, the latter finding their chief sphere of application, however, in the symptomatic treatment of the complications of obesity.

One can conveniently distinguish three degrees of obesity that have been aptly characterized by a German writer as the enviable, the comical and the pitiable stage, the first presenting itself as a pleasing rotundity, the second as a jovial embonpoint of the Falstaff type, the third as a sad, unwieldy and, to our Caucasian tastes, disgusting deformity. Each of these three forms requires particular treatment. In the first form no attempt need be made to reduce the amount of fat, but every effort should be put forward to prevent its further development, particularly if premonitory signs of complications about the thoracic or abdominal organs begin to make their appearance. In the second and third forms, however, it becomes necessary to institute more or less energetic restrictions with the object in view of causing a loss of fat.

The laity and many physicians to this day direct their attention chiefly to the quality or the preparation of the food in reducing obesity. Certain articles are said to form fat and others not. This idea is erroneous. Broadly speaking, carbohydrates and fat foods should be reduced, and not the albumins. This rule is to be observed not because albumin forms less fat than carbohydrates or fats, but because the reduction of the albumin below certain normal average requirements, as will be explained below, is a dangerous and precarious procedure, whereas the fats and carbohydrates can be much reduced without much detriment to the individual.

One may say broadly and with certain reservations that will be presently discussed that any article of food can form fat, according to its caloric value; that the introduction of more calories either in the form of albumins or fats or of carbohydrates than are required to maintain normal nutritive equilibrium may lead to the deposit of fat in the tissues, whereas the introduction of less calories leads the organism to promptly attack chiefly its fat reserve to make up the caloric deficit.

THE SCIENCE OF REDUCTION CURES.

The first step, then, in instituting a reduction cure should be to determine the normal caloric requirement of the individual, assuming that he were not obese. This can be done by consulting the following table on which will be found the normal average weight for individuals of a certain height, both men and women:

Age (Years)	Men		Women	
	Height (In Meters)[1]	Weight (Kilogrammes)[1]	Height (in Meters)	Weight (Kilogrammes)
0	0.5	3.2	0.49	2.91
1	0.7	9.45	0.69	8.79
2	0.77	11.34	0.78	10.67
3	0.86	12.47	0.85	11.79
4	0.92	14.23	0.92	13.00
5	0.99	15.77	0.98	14.36
6	1.05	17,24	1.10	16.01
7	1.11	19.10	1.15	17.54
8	1.16	20.76	1.18	19.08
9	1.22	22.65	1.19	21.36
10	1.28	24.52	1.25	23.52
11	1.33	27.1	1.30	25.7
12	1.39	29.8	1.35	29.8
13	1.44	34.4	1.40	32.9
14	1.49	38.8	1.45	36.7
15	1.55	43.6	1.49	40.4
16	1.59	49.7	1.54	43.6
17	1.63	52.9	1.56	47.3
18	1.66	57.9	1.56	51.0
20	1.67	60.1	1.57	52.3
25	1.68	62.9	1.58	53.3
30	1,68	63.7	1.58	54.3
40	1.68	63.7	1.58	55.2
50	1.67	63.5	1.53	56.2
60	1.63	62.9	1.52	54.3
70	1.62	59.5	1.52	51.3

By multiplying this weight by 30 to 35[2] the approximate caloric requirement can be obtained.

Assuming that the patient were 1.7 meters tall, then, according to the table he should weigh about 61 kilos and would normally require about 61 × 35 = 2,135 calories a day.

The diet should now be arranged in such a way, with the aid of tables giving the caloric value of different articles of food, that this number of calories is furnished, and not more nor less. This constitutes the mildest form of underfeeding, the caloric intake being insufficient only relatively, i. e., as compared to the abnormal bulk of the patient. If the patient does not lose weight on such a diet containing the full normal caloric requirement, then it is necessary to reduce the caloric intake still further.

THE THREE DEGREES OF REDUCTION CURE.

It is convenient in obesity, as in diabetes, to arrange three degrees of reduction cures. In the first degree the caloric requirements are reduced to 4/5 of the normal, in the second to 3/5, and in the third to 2/5. Calculating this for an individual, e. g., requiring 2,500 calories as the normal, the first degree calls for the administration of foods possessing a caloric value of about 4/5 of 2,500 or 2,000, the second 3/5 of 2,500, or 1,500, and the third.

---

* Read before the Section on Medicine of the Illinois State Medical Society, Springfield, 1906.

1. One meter = 39.37 inches or 1 yard 3 1/3 inches (English). One Kilogramme = 2 lb. 3 oz. 2 dr. (avoirdupois).

2. For measuring the nutritive value of the different classes of foods, the term "calorie" has been imported from the realm of physics. A calorie is that amount of heat that is needed to raise the temperature of 1 kilo of water 1 degree (Celsius). Each article of food, it has been found, in process of metabolism (i. e., of assimilation, oxidative disassimilation and elimination) in the body generates a definite quantity of heat, or the mechanical equivalent of this heat in labor. Expressed in calories:

1 gr. of proteid furnishes....................4.1 cal.
1 gr. of carbohydrate furnishes..............4.1 cal.
1 gr. of fat furnishes ....9.3 cal.

It has further been determined that a normal adult requires from 30 to 35 calories a day per kilo of body weight, and that these calories can be furnished by any one or all of the three classes of food vicariously. (Croftan: Clinical Urinology, page 73.)

of about 2/5 of 2,500, or about 1,000. The popular cures of Banting, Oertel, Epstein, Hirschfeldt and others possess a caloric value lying between 1,100 and 1,600 only; they are consequently reduction cures of the third degree and, as will be presently shown, usually far more severe than is safe or necessary.

The rapidity with which fat is lost in these three degrees of reduction cures varies.

In the first degree the loss is usually very slow, the patients rarely losing more than two or three pounds a month, and even this slight reduction can only be accomplished if they indulge at the same time in considerable physical exercise. This four-fifths diet is useful chiefly in preventing the further increase of fat in subjects who are showing a tendency to obesity. It is eminently suitable for continued use and does not require any great sacrifice on the part of the patient. It is hardly ever necessary to calculate the caloric value carefully in this light form, for all one has to do is to allow meat only once a day, to reduce the amount of fat and starchy and sweet foods somewhat, to restrict or forbid alcoholic beverages, to give "filling" foods of small caloric value (see below) in abundance, to restrict the liquid intake to 1 to 1¼ liters of fluid a day, and to order abundant physical exercise.

The second degree is also particularly useful for continued use. It should be adopted (1) for very strong and very fat subjects who want to get rid of surplus fat and can safely indulge in very active physical exercise; (2) for individuals who are not only fat, but in whom complicating disorders about the heart, arteries, bronchi or digestive apparatus render it impossible to "work off" fat by exercise, so that the necessary reduction of the fat must be brought about in the beginning, i. e., until the complications improve or disappear, by dietetic restrictions alone; (3) for strong fat individuals who can not at once tolerate a third degree reduction cure without developing alarming symptoms of weakness, particularly about the circulatory and muscular apparatus; in the latter class of cases the three-fifths reduction cure is used as a transition diet to the third degree and is intended to gradually accustom the patients to restrictions of a more severe order. This second degree, too, leads only to relatively slight and slow losses of fat, more than six to ten pounds rarely being sacrificed a month.

The third degree, finally, is a rapid reduction cure. It must be carefully supervised and would best be carried out in an institution. Here we frequently find that the loss of fat is rapid in proportion to the obesity of the individual, showing that it is the surplus adipose tissue that is being sacrificed and not the albumins of the body. Combined with systematic exercise and drink restriction (see below) as much as thirty pounds a month can be lost with safety. A reduction cure of the third degree should never be carried out for indefinite periods, and six weeks is the longest time during which this serious restriction of the patient's nourishment should be allowed. In many cases the intermittent plan will have to be adopted, i. e., the patients are placed for four to six weeks on the rigid plan, then for a month or two on the second degree, and then back again to the rigid diet until the desired loss of flesh has been produced. It will be seen that here very similar principles are adopted as in the reduction of diabetic glycosuria.

While it is true that energetic starvation often rapidly leads to a loss of weight greater than that which can be accomplished by more gradual and more moderate means, such rapid reduction cures, as typified, for instance, by the Banting system, which is so popular among the laity, are rarely without serious danger to the various organs that are commonly involved in advanced degrees of obesity, nor are the results, broadly speaking, permanent. In very young people and in very old people rapid reduction cures should be altogether eschewed; for in *children and in adolescent* subjects irreparable damage is often done, growth stunted and serious complications engendered, whereas in old people the results are usually very unsatisfactory and never without danger, while the effects at best are exceedingly transitory.

THE ART OF REDUCTION CURES.

The question in regard to the kind of food that should be allowed in instituting any reduction cure and its mode of preparation has been the subject of much controversy for many years. The greatest care should be exercised, as mentioned above, not to attack the albumin content of the body; hence it is important to give the known minimum necessary to maintain adequate nutrition—and not less—to all cases in order that the patients may not be forced to consume the albumins of their proper tissues. This minimum lies somewhere between 60 and 80 grams a day, so that this amount, which corresponds approximately to 400 to 600 grams of lean meat, at least should be invariably supplied. No difficulty should ever be experienced in meeting this requirement. Notwithstanding the claim of some doctrinaires, excessive meat feeding is not only unnecessary, but may be directly harmful in instituting reduction cures. A great deal will depend on the tastes and the previous habits of the patients. If they have not been excessive meat eaters, there is no reason why they should be forced to eat much meat. If they have been abundant meat eaters, they may safely continue meat eating, provided the intake is not so large that the total caloric value of the food is increased above the prescribed and calculated limit.

The next question to decide is whether the carbohydrates or the fats are to be chiefly restricted. Here, again, a very virulent controversy has been going on for many decades. This is not the place to enter into a discussion of the merits or demerits of the different theories advanced. From a practical standpoint it is best to reduce the fats and to give relatively large quantities of such carbohydrate foods as possess bulk; for the latter, as a rule, incorporate a small caloric value, while, at the same time, fully satisfying the patient. The idea that fat forms fat in the body more than carbohydrate has been shown to be erroneous; carbohydrates, in fact, seem to be more readily deposited as reserve fat in the tissues than the fat that is eaten.

To summarize, therefore, the diet in reduction cures should be arranged in such a way that the individual receives an amount of albuminous food, incorporating at least 60 to 80 grams of albumin. This is necessary in order to maintain nitrogen equilibrium and to protect the tissue albumins. The remaining number of calories that are to be supplied may be vicariously furnished either in the form of fats or carbohydrates. Of the two the carbohydrates, however, especially if they are voluminous, should be given the preference.

The distribution of the meals is sometimes of importance. The best plan is to give three meals during the day and, in addition, two or three small meals between, the latter preferably consisting of articles like bouillon, coffee or a little fruit, that all possess a small caloric value. They serve the purpose of keeping the patient comfortable, avoiding disagreeable sensations of weakness and gastric emptiness and at the same time preventing the patient from becoming too ravenously hungry at meal times and consequently overeating.

THE RESTRICTION OF LIQUIDS.

One other important principle must be observed in feeding diabetics, viz.: the liquid intake should be restricted. Nothing is easier than to rapidly reduce the weight of an obese subject by restricting the liquid intake to a minimum. This loss of weight becomes particularly apparent during the first four or five days of the ure. It is due, in the first place, to a direct loss of water rom the tissues; in the second place, to the fact that an dividual drinking very little water does not eat as ich as one taking a normal amount of liquid. The reiction, therefore, in the beginning is a useful procedmore for physic that for physiologic reasons; for patients, when they notice how rapidly they are g flesh, acquire that confidence in the method that important if they are to carry out the more or less isagreeable and stringent orders that must be enforced. No permanent effects, however, are obtained from this restriction of liquids, and the patients regain the lost weight as quickly as they lost it so soon as they begin to increase water drinking. Nevertheless, even in cases in which the restrictions are to be continued for a long time, a reduction of the total liquid intake to about 1 to 1½ liters in the 24 hours is a useful adjuvant. It renders it easier for the patients to live up to their restrictions and it is also beneficial in advanced cases of obesity with complications, because it spares the heart and the kidneys. In cases, finally, that suffer from excessive sweating, the restriction of liquids is a very useful procedure to remove this disagreeable symptom.

SPECIAL ARTICLES OF FOOD.

Alcohol may be administered to obese subjects, provided the caloric value of each gram of alcohol is carefully included in the calculation. It should be allowed particularly in cases that have been accustomed to a little alcohol all their lives; for here withdrawal of alcohol is not only an unnecessary hardship, but may even constitute a source of danger, especially if a weakened heart is suddenly robbed of its accustomed stimulus.

In selecting meats for obese subjects, lean varieties should be given the preference. Lean meat contains about 20 per cent. of albumin and 1.5 to 2.0 per cent. of fat, so that 100 grams of lean meat, weighed raw, furnish about 100 calories. It is necessary, of course, that the meat should be prepared in a very simple way, i. e., it should be either stewed, roasted or broiled. All meats that are prepared by frying or served as ragouts or with bread crumbs, sauces and gravies contain incalculable amounts of fat, so that their caloric value may assume very large proportions. It is always best, therefore, to forbid the use of any but lean meats, plainly prepared.

Among the animal foods that an obese subject can eat with impunity are a number of delicacies that are taken only in small quantities and, on account of their flavor, are very agreeable additions to the diet; thus, according to a table published by von Noorden, 100 calories are ontained in:

45 grams of caviar.
40 grams of sardines.
100 grams of boiled lobster.
160 grams of crab meat.
120 grams of oysters (equal to about 14 to 18 oysters of
medium size).
25 grams of paté de foie gras.

Cheese also serves a useful purpose, for, taken even in very small quantities, it is very filling. Thus Swiss cheese, American cheese, Cheddar and Chester cheese contain about 28 per cent. of albumin, 30 per cent. of fat and 2 per cent. of carbohydrate, and 25 grams of these cheeses furnish about 100 calories.

Milk is a very useful addition to the bill of fare of obese subjects, provided its caloric value and the water it contains are included in the calculation. One hundred c.c. of milk furnish about 60 calories. This amount can safely be allowed with tea and coffee. Buttermilk is still more useful, for 100 c.c. of this only contain from 40 to 45 calories and a whole quart about 250 calories.

Thin soups and bouillon and beef tea are exceedingly useful articles, for their caloric value is practically 0. They are filling, they taste well, and the patient eating a large plate of bouillon imagines that he is getting something of value to eat.

Rich sauces, as stated above, should be absolutely forbidden, because they are made of large quantities of fat, flour, eggs, so that their caloric value can hardly be calculated. Articles made of flour or rice, like noodles and macaroni, puddings, etc., should not be allowed in the strict reduction cures. In the second and third degrees, however, small quantities may be permitted as a relish. If they are given, each tablespoonful of these articles should be figured as representing about 30 calories.

Potatoes are also permitted, provided they are given in small quantities and are either baked, boiled or mashed. One hundred grams of potatoes contain about 1.5 per cent. of albumin and 18½ per cent. of carbohydrate and possess a nutritive value of 80 calories.

Among the vegetables, those varieties that grow underground as well as those that grow in pods should be forbidden or restricted, because they contain very large and varying amounts of carbohydrates. If they are permitted at all in the lighter reduction cures, their caloric value should be carefully determined. All the other vegetables are exceedingly useful articles of diet in obesity, for they possess a very small caloric value in proportion to their bulk and consequently fill the stomach and rapidly produce a sense of satiety; incidentally they act favorably on the function of the bowel. They should be served only boiled in salt water, without the addition of cream, butter, flour, etc. If flour or fats are used in preparing vegetable dishes, the amounts should be carefully weighed and their caloric value considered.

Fruits of all kinds, with the exception of bananas, sweet grapes, figs, dates, raisins, are permitted without reserve; they, too, are very filling and act well on the digestive apparatus and constitute a great relish without, at the same time, possessing a high caloric value. About 100 calories are contained in 220 to 250 grams of fruit.

The use of bread is permitted in obesity, only, however, if the bread is carefully weighed and its caloric value considered. Here the same rules obtain as in the feeding of bread to diabetics, i. e., those varieties that are made of vegetable albumin (gluten breads, aleuronat bread, etc.) are particularly useful if they are baked so as to become fluffy and voluminous, for they satisfy the eye and the mind and are filling without possessing a very large caloric value.[3]

---

[3] Most so-called diabetic breads contain approximately 50 per cent. of carbohydrate. The vegetable albumins (aleuronat, roborat, plasmon, gluten) all contain about 5 per cent. of carbohydrate. These breads are made from such flours plus a certain amount (one to four parts) of ordinary flour. They should, hence, only be used as an equivalent for white bread in the proportion of about 4 to 1. Their indiscriminate use, which is so popular among the laity, who imagine that these breads can safely be taken ad libitum, is, therefore, to be condemned as dangerous. They fulfill a useful purpose, however, owing to the fact that much more of the various diabetic breads can be eaten as of ordinary white or rye bread and still no greater amount of carbohydrate be administered.

A great many mineral waters enjoy deserved popularity in the treatment of obesity, notably the waters of Kissingen, Vichy, Homburg, Carlsbad and Mariensbad. It is a futile task, however, to attempt the reduction of obesity by the use of these waters alone. It is possible, of course, by producing profuse watery diarrhea with the aid of these waters to cause a considerable loss of water from the tissues and hence a reduction in the weight of the patient. This practice is of some use for psychologic reasons, because the rapid loss of weight in the beginning of the treatment makes a great impression upon the patient and renders him more willing to follow directions later on. The indiscriminate use of mineral waters is, however, to be condemned; for if the diarrhea is allowed to persist too long the effect is without doubt weakening, and this practice, moreover, especially in obesity, reacts unfavorably upon the blood pressure and the heart.

These patients, it is true, do very well, as a rule, in resorts in which these waters are taken, but the effects are to be attributed only in a very small part to the drinking of the particular water (witness the indifferent effects obtained from the use of these waters of salts at home) and in much greater part of the careful and strict regulations in regard to exercise,[4] general mode of life and diet that the patients undergo much more willingly and conscientiously at a watering place than at home. Fully as useful, probably safer, and by all means cheaper is the treatment of obesity in an institution where a like control can be exercised over the patient's diet and habits.

100 State Street.

TREATMENT OF PROGRESSIVE ATROPHY OF THE OPTIC NERVE DUE TO ACQUIRED SYPHILIS.

BY SUBCONJUNCTIVAL AND INTRAVAGINAL INJECTIONS OF SUBLIMATE OF MERCURY.*

CHARLES STEDMAN BULL, A.M., M.D.
NEW YORK.

The treatment of syphilitic atrophy of the optic nerve is a subject which taxes all our patience and ingenuity. So universally unfavorable is the prognosis that the ophthalmic surgeon is ready to grasp almost any means which promises a solution of the problem. All surgical interference with the optic nerve itself, such as incision of the nerve sheath in several places, or elongation of the nerve by stretching, has yielded such imperfect and inconstant results that it can not any longer be recommended and has been abandoned. The same may be said of sympathectomy, which has so recently been vaunted as a remedy for atrophy. The constant current, and even static electricity, have been faithfully tried and have usually proved unavailing. Much has been claimed for the treatment by vibratory massage, but I have never personally known of a case of atrophy which has been permanently, or even temporarily, benefited by this method.

In advanced cases of syphilitic atrophy of the nerve I believe mercury administered internally to be useless, and it may do real injury. Roborant treatment, directed to the general health, in these cases sometimes aids in retarding the degenerative process.

As we all know, there are clinically several forms of atrophy of the optic nerve: the partial, the total, the stationary and the progressive. The cases of partial atrophy are generally stationary. The instances of progressive atrophy met with in syphilitic patients are the most unfavorable. These cases are always bilateral, and the pupillary disturbance, or loss of reflex action of the iris, is often observed within the first year after infection has occurred, and may, therefore, be regarded as a warning of impending atrophy. It may accompany beginning optic atrophy before the loss of sight is sufficient to explain it. The evolution of an optic atrophy is very irregular, and total blindness is often complete in one or two years, though occurring usually sooner in one eye than the other; and some central fibers may remain intact during the remainder of the patient's life. It is in this small minority of cases that we are prone to attribute the arrest to whatever method of treatment we are at the time employing. It is impossible to say how many of these cases of arrest of the degenerative process are due to the treatment adopted, and a therapeutic effect can only be expected when the optic nerve fibers have been merely compressed by the hypertrophy of the connective tissue framework of the nerve.

USE OF SUBLIMATE INJECTIONS.

Subconjunctival sublimate injections have been employed in the treatment of optic nerve atrophy by various authorities, but hitherto with but little success.

Darier is probably correct in saying that they are contraindicated for the time being whenever the absorption of the fluid by obstructed lymph-channels is rendered difficult or impossible by a circulatory stasis, for in such cases they are irritating and more harmful that useful. It is going too far, however, to say that as an anti-syphilitic method subconjunctival sublimate injections have a rapid and intense action on specific ocular manifestations at all stages, for in most of the chronic cases of deep-seated eye trouble, notably of the optic nerve, this does not hold true. The statement that the chief contraindication to subconjunctival injections lies in an engorgement of the circumcorneal circle of vessels is true only of the lesions of the anterior parts of the eye, and does not apply to optic nerve atrophy.

The subconjunctival injection of the various salts of mercury is more or less painful, the cyanid being the most so. In endeavoring to prevent or diminish the pain of mercurial injections do not add a solution of cocain to the sublimate solution, for the cocain is decomposed at once. Akoin lessens the pain, but is precipitated by the least alkalinity of the solution. It is better to inject a few drops of a 5 per cent. solution of cocain under the conjunctiva five or ten minutes before the sublimate injection is made. If akoin is used a 1 per cent. solution is of sufficient strength.

---

[4] The element of muscular exercise is second in importance only to the regulation of the diet in obesity. *It can readily be calculated* that a certain amount of muscular exercise causes a loss of a certain amount of fat. Oertel, who has studied, more than anybody else, the effect of graduated exercise, especially graduated hill climbing, on obesity and the action of the heart, based his original recommendations on definite calculations as follows: Assuming that a man weighing 60 kilograms ascends an elevation each day of 100 meters, then the labor performed is equal to $60 \times 100 = 6.000$ kilogrammeters; as a matter of fact, much more energy is expended, for the external labor produced represents only about 30 per cent. of the total energy developed; thus such an individual in a day develops fully 20.000 kilogrammeters of energy. As 425 kilogrammeters of muscle work require 1 calorie, 20,000 kilogrammeters require 47.06, and this amount of caloric value is furnished by $\frac{47.06}{9.3}=5.06$ of fat. It will be seen, therefore, that such an individual must consume 5.06 of body fat to raise his body 100 meters. It is immaterial, *of course, according* to the laws of the conservation of energy, whether or not this elevation is reached within a short time or within a long time, by a vertical path or by a long series of inclined paths.

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-seventh Annual Session, June, 1906.

Zossenheim[1] has used injections of sublimate in many cases of optic nerve atrophy, but reports not a single case of encouraging results.

Dufour prefers sublimate to cyanid of mercury, of the strength of 1 to 3,000, and never injects more than half a syringeful. He keeps his patient in bed for two days with both eyes bandaged. If there is no improvement after the eighth injection he gives up the treatment.

Senn[2] prefers the cyanid of mercury to the sublimate in cases of optic atrophy, but reports no favorable results.

METHOD OF TREATMENT.

The principles of subconjunctival injection laid down by Darier would apparently apply only to the anterior segment of the eye, and their effect on the aqueous humor through Schlemm's canal and Fontana's space. If, however, the efficacy of subconjunctival injections depends on the absorption of the injected substances, the moment an isotonic equilibrium is established. there is no reason why this condition may not be induced in the posterior channels of filtration by subconjunctival injections far back of the equator of the eye, and thus an effect be produced theoretically on the optic nerve. These posterior injections must not be made near the limbus, nor too deep under the conjunctiva, where the capsule of Tenon is intimately attached to the sclera. In making the injections it is better first to incise the conjunctiva and separate it for some distance from the sclera by a strabismus hook and then introduce the needle far back, hugging the sclera, and inject slowly. There is less pain from the injection if the episcleral tissue is not injured.

I use a Pravaz syringe with a fine needle of iridised platinum, which can be sterilized by passing it through a gas flame. The liquid to be injected must be sterilized by boiling and allowed to cool to blood temperature and is then injected. The injection is made in the superotemporal region, tangentially to the sclera, and the liquid must not be allowed to extend toward the limbus. Hence the value of dissecting the conjunctiva from the sclera in the direction backward toward the optic nerve entrance before the injection is made.

This method of treatment was carried out on twenty-five cases of progressive atrophy of the optic nerve, due to constitutional syphilis. They were cases of simple atrophy and were not preceded by any intraocular signs of papillitis or neuritis. They were all private patients under my own care until the treatment was abandoned as useless. They had all been subjected to one or more full courses of thorough anti-syphilitic treatment by skilled syphilologists, which had been carried out for a varying period from one to two years, or until no constitutional symptoms had appeared for some time.

The presence of tabes or disseminated sclerosis was so far as possible excluded.

Before the treatment by subconjunctival injections was begun the patients were subjected to a course of strychnia by hypodermic injections, pushing the dose of the drug to the extreme of toleration. In every case the observations, the testing of the vision and the visual field were made by myself. Some of the cases had been previously treated by the interrupted current and by static electricity by other physicians, and two of them had undergone a prolonged treatment by vibratory massage without any benefit.

The shortest interval between the occurrence of the initial lesion and the first failure of vision was two years, and the longest interval was twenty-three years. From investigations made by Januskiewicz, covering many cases, it has been found that the shortest interval in any reported case between the contraction of the disease and the failure of vision was six months, and the longest was twenty-nine years. The failure of vision occurred most frequently from five to ten years after the appearance of the chancre.

RESULTS OF TREATMENT.

In none of the cases was there any permanent improvement of the vision by the treatment noted, and in only three was there any temporary improvement. In no case did the injections cause any acceleration of the loss of sight.
